**Image formation occurs when a sensor registers radiation that has interacted with physical objects.**

It consists of several components:

- **An imaging function** - a fundamental abstraction of an image
- **A geometric model** - projection of the 3D world into 2D representation
- **A radiometric model** - describes how light radiated from the object is measured by the imaging sensor.
- **A color model** - describes how different spectral measurements are related to image colors

# Imaging function

188	186	188	187	168	130	101	99	110	113	112	107	117	140	153	153	156	158	156	153

is an imaging function defined on the area  $\Omega$  and takes values in the positive real numbers:

$$I : \Omega \subset \mathbb{R} \rightarrow \mathbb{R}_+; (x, y) \mapsto I(x, y).$$

Because of the discretization we have:

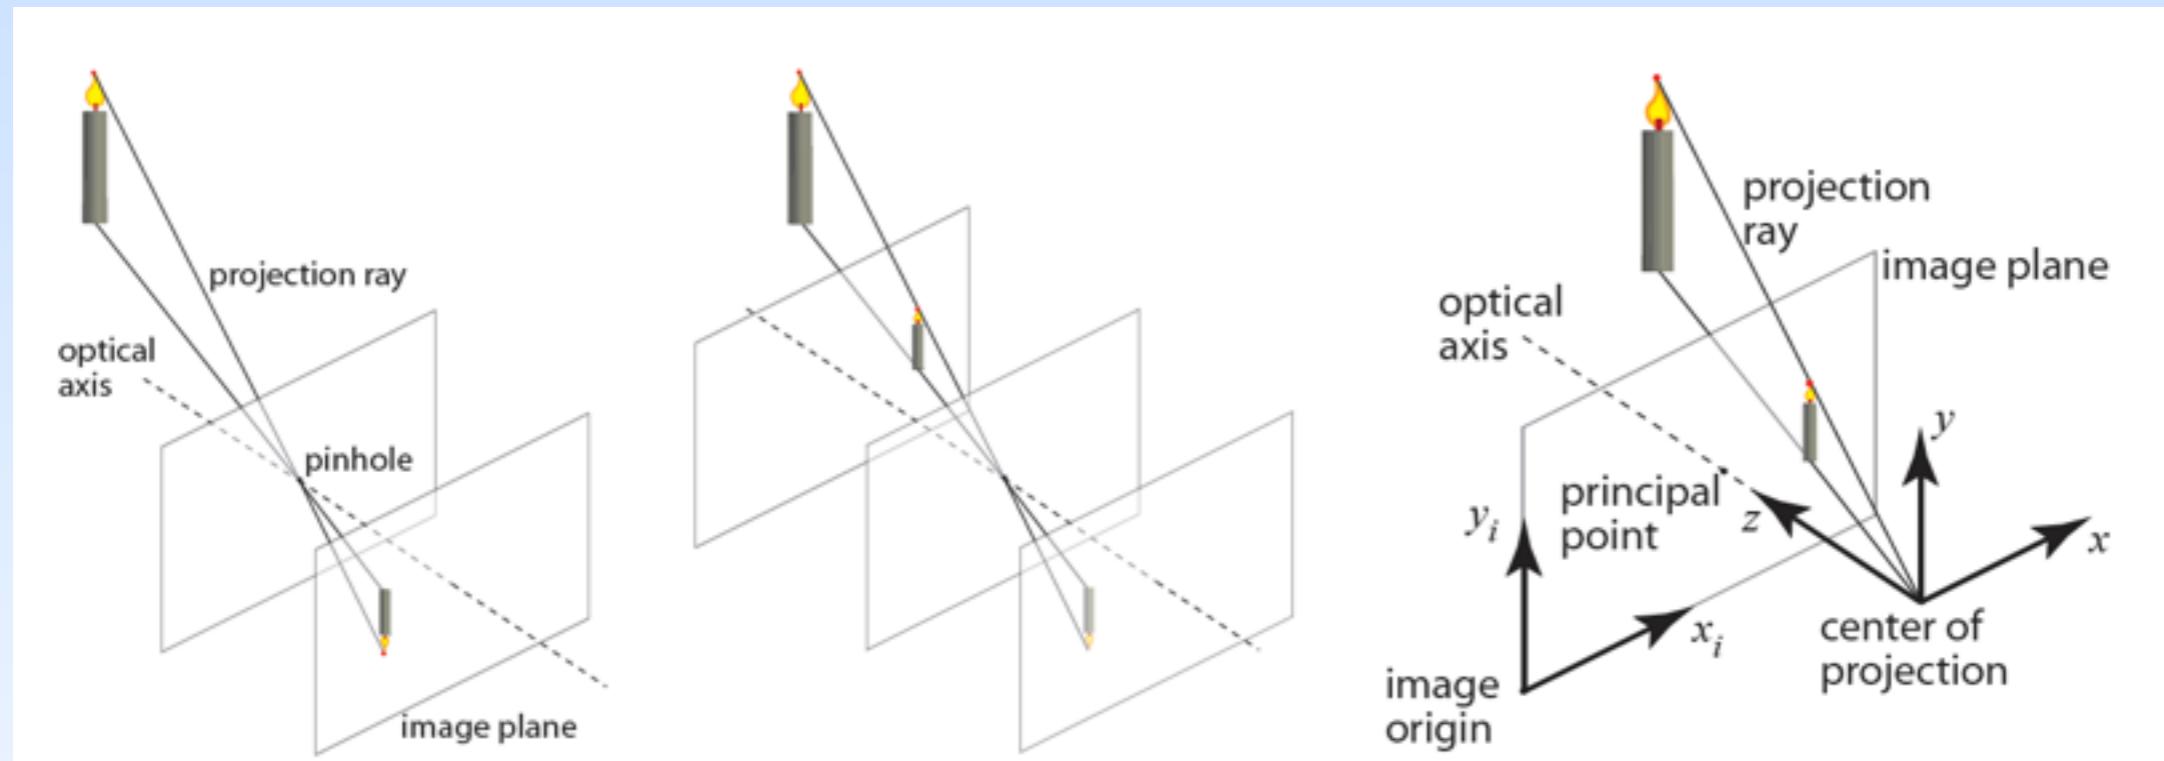

$$\Omega = [1, 640] \times [1, 480] \subset \mathbb{Z}^2, \quad \mathbb{R}_+ = [0, 255] \subset \mathbb{Z}_+$$

Or in general:

$$I = I(x, y) = \{I_R(x, y), I_G(x, y), I_B(x, y)\}$$

# Geometric model

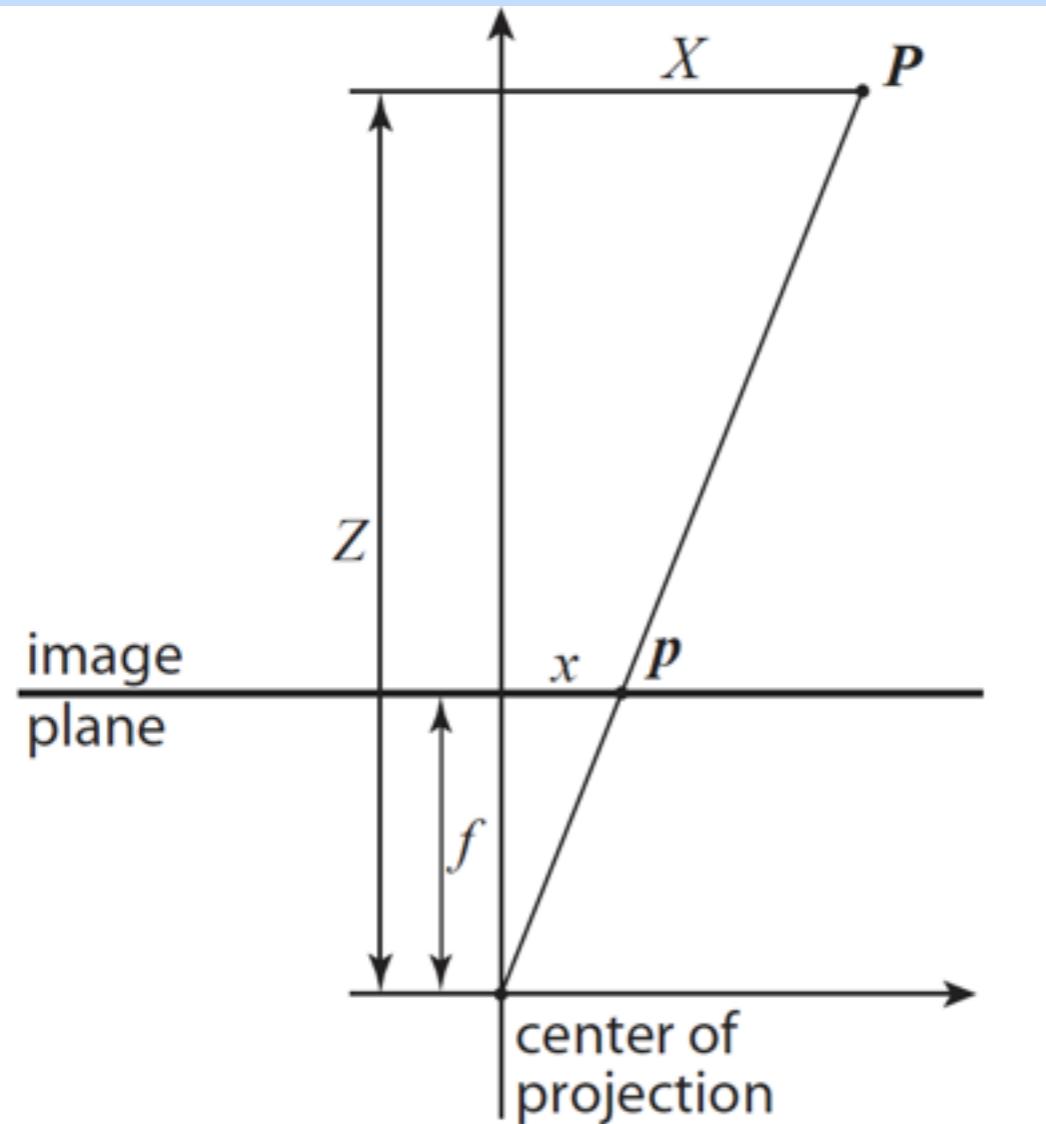

## The pinhole camera model

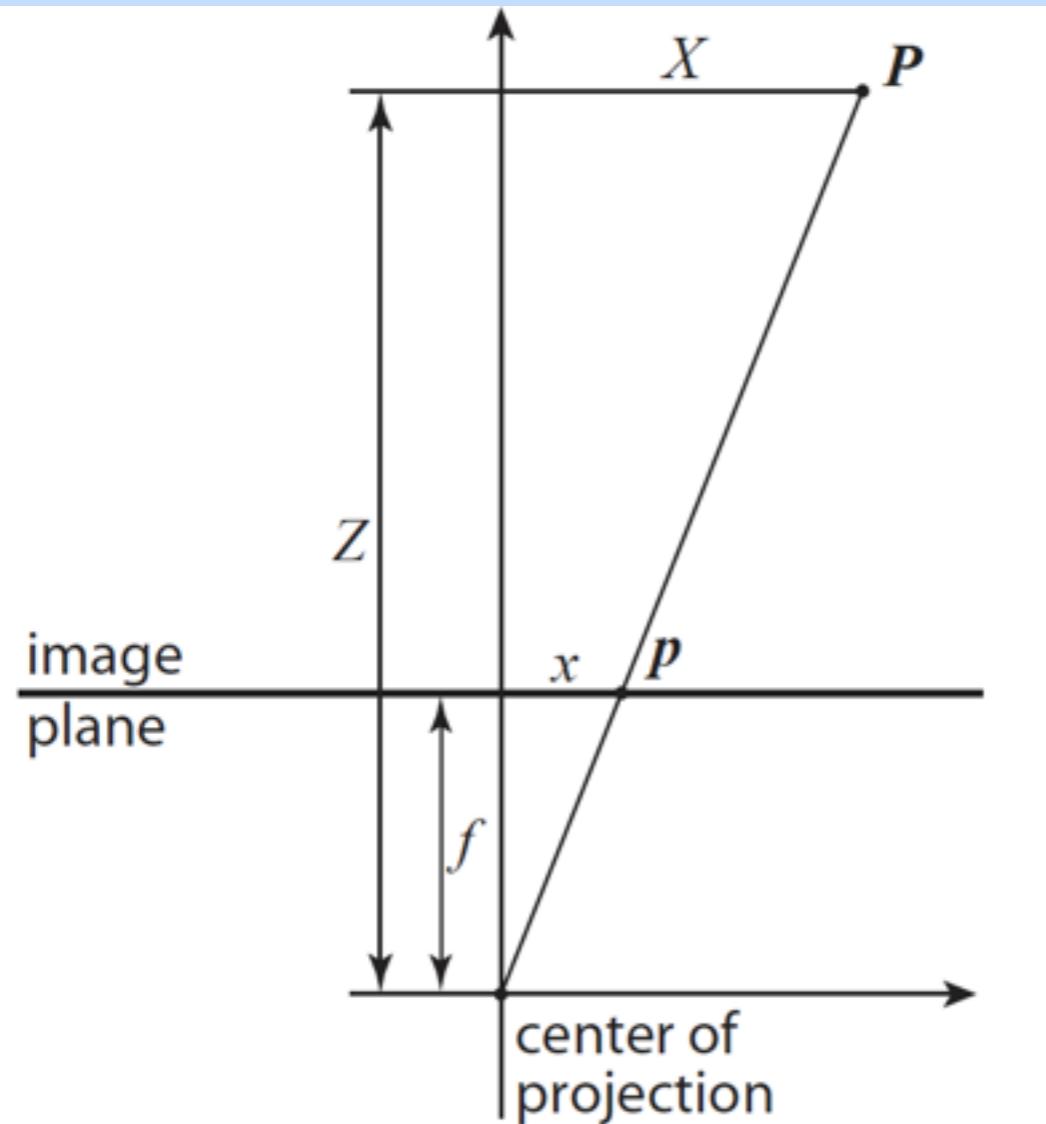

(a) Projection geometry (b) Image plane in front. (c) Notations for pinhole camera model

# Perspective projection

---

# Perspective projection

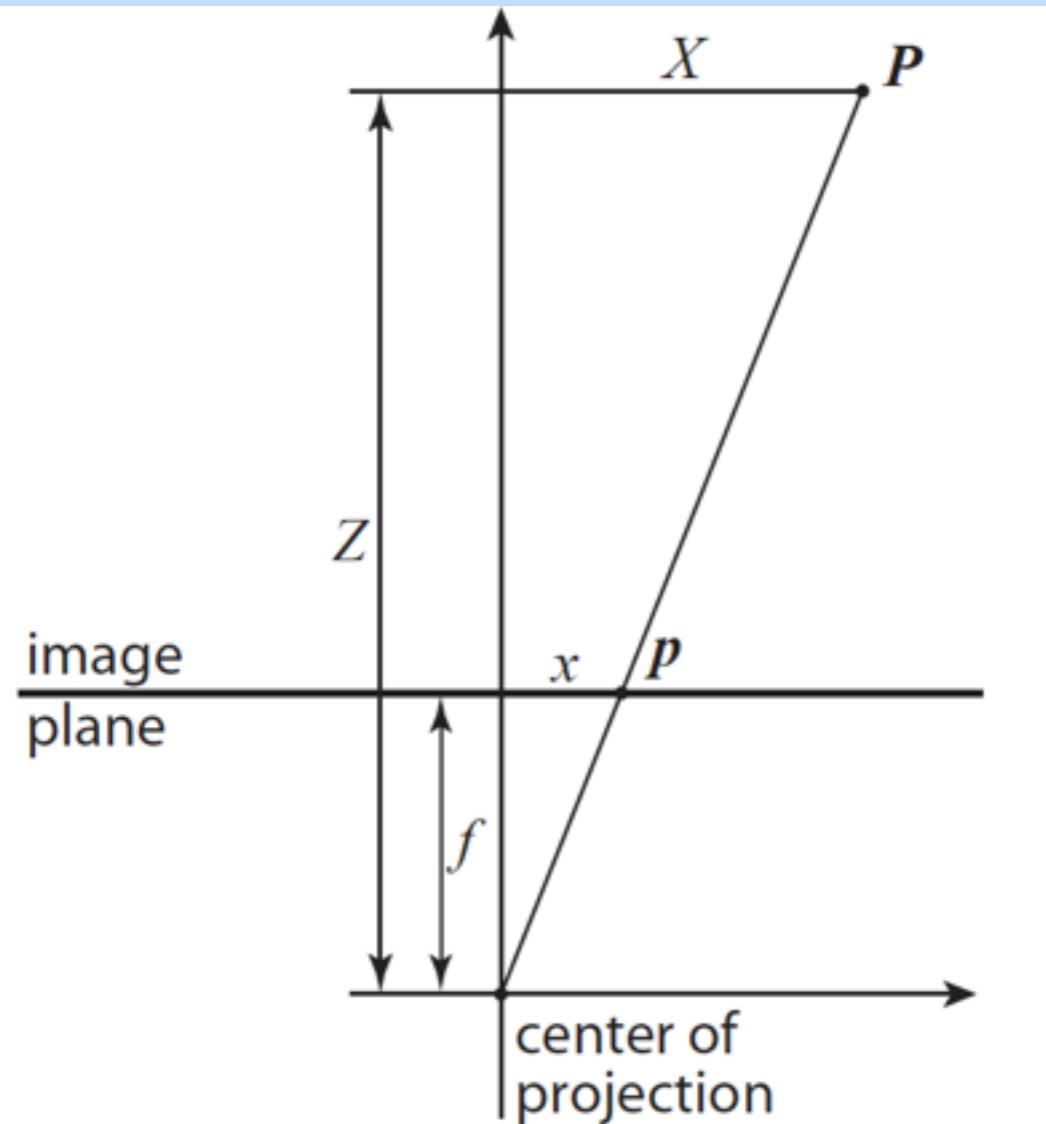

World coordinate system is identical to the camera coordinate system with the origin at the center of projection.

Under perspective projection, the object point with world coordinates projects to the image point with *ideal image coordinates*:

*Ideal image coordinates* are expressed in terms of the image coordinate system with the origin at the optical center.

# Perspective projection

World coordinate system is identical to the camera coordinate system with the origin at the center of projection.

Under perspective projection, the object point with world coordinates  $P = (X, Y, Z)$  projects to the image point with ***ideal image coordinates***:

$$x = f \frac{X}{Z} \quad y = f \frac{Y}{Z}$$

***Ideal image coordinates*** are expressed in terms of the image coordinate system with the origin at the optical center.

# Image processing

---

Image processing is in general not part of Computer Vision, but it is sometimes a very necessary preprocessing step.

Image processing provides a number of methods to convert an image into something suitable for analysis.

There are two main approaches:

- Processing in the spacial domain:
  1. Point processing (brightness, contrast, histogram equalization etc.)
  2. Filtering
- Processing in the frequency domain: Fourier transform

# Image processing

# Filtering

---

Original image

Blurred image

From the draft of Szeliski's book: <http://research.microsoft.com/en-us/um/people/szeliski/Book/>

Filtering is based on neighborhood operations.

# Correlation and Convolution

---

These are two simplest filtering operations and they have two key properties:

- shift invariance** (the same operation is performed at every location in the image)
- linearity** (every pixel is replaced with the linear combination of its neighbors)

# Example

$$\ast \begin{bmatrix} 1 & 1 & 1 \\ 1 & -8 & 1 \\ 1 & 1 & 1 \end{bmatrix} =$$

# Expressing convolution

---

Mathematically convolution can be expresses as:

$$J(x, y) = H * I = \sum_{i=-\infty}^{+\infty} \sum_{j=-\infty}^{+\infty} H(i, j)I(x - i, y - j)$$

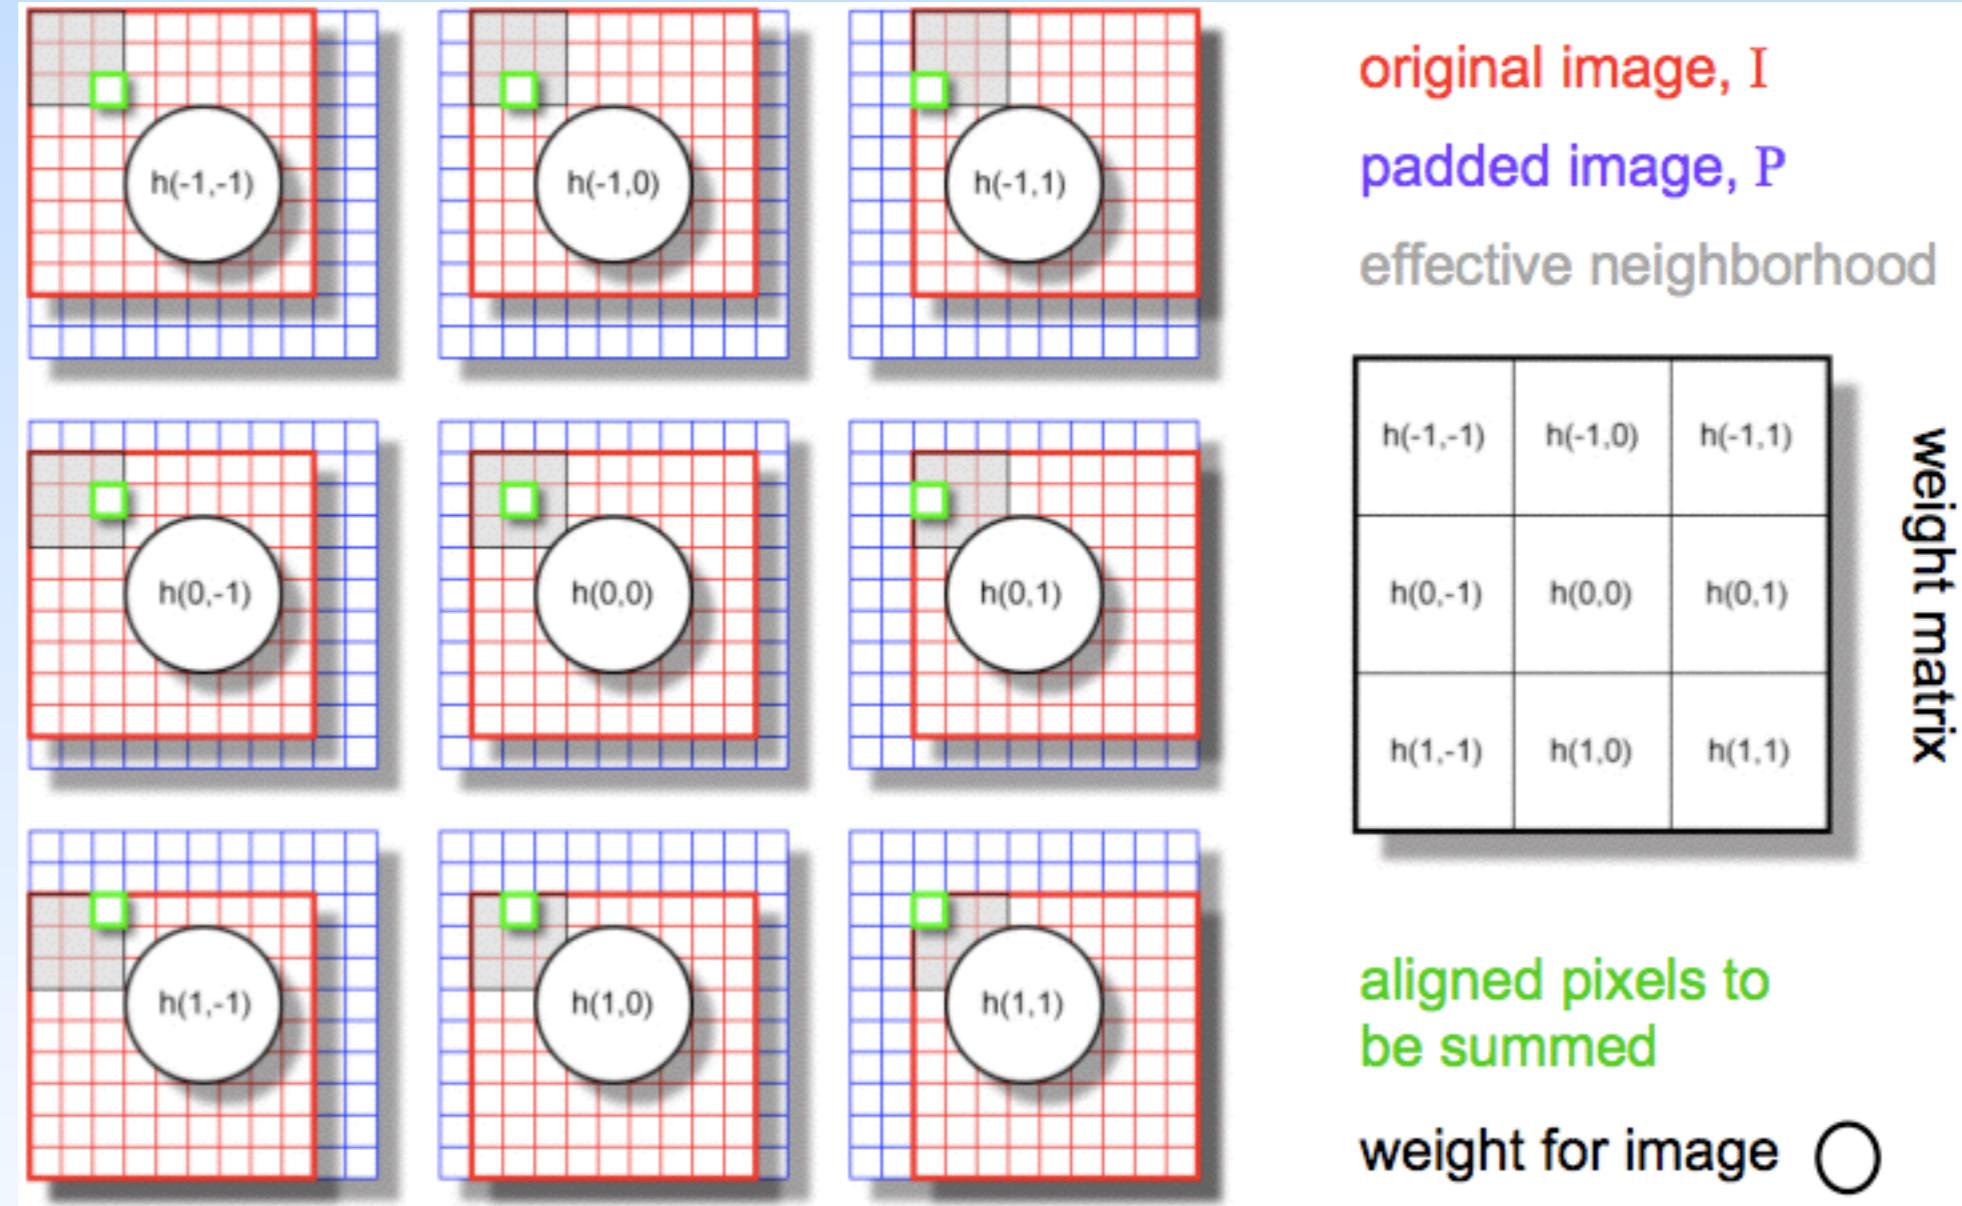

if we change the variables  $i \leftarrow x - i$  and  $j \leftarrow y - j$   
we get:

$$J(x, y) = H * I = \sum_{i=-\infty}^{+\infty} \sum_{j=-\infty}^{+\infty} H(x - i, y - j)I(i, j)$$

with the image and the kernel playing  
interchangeable roles.

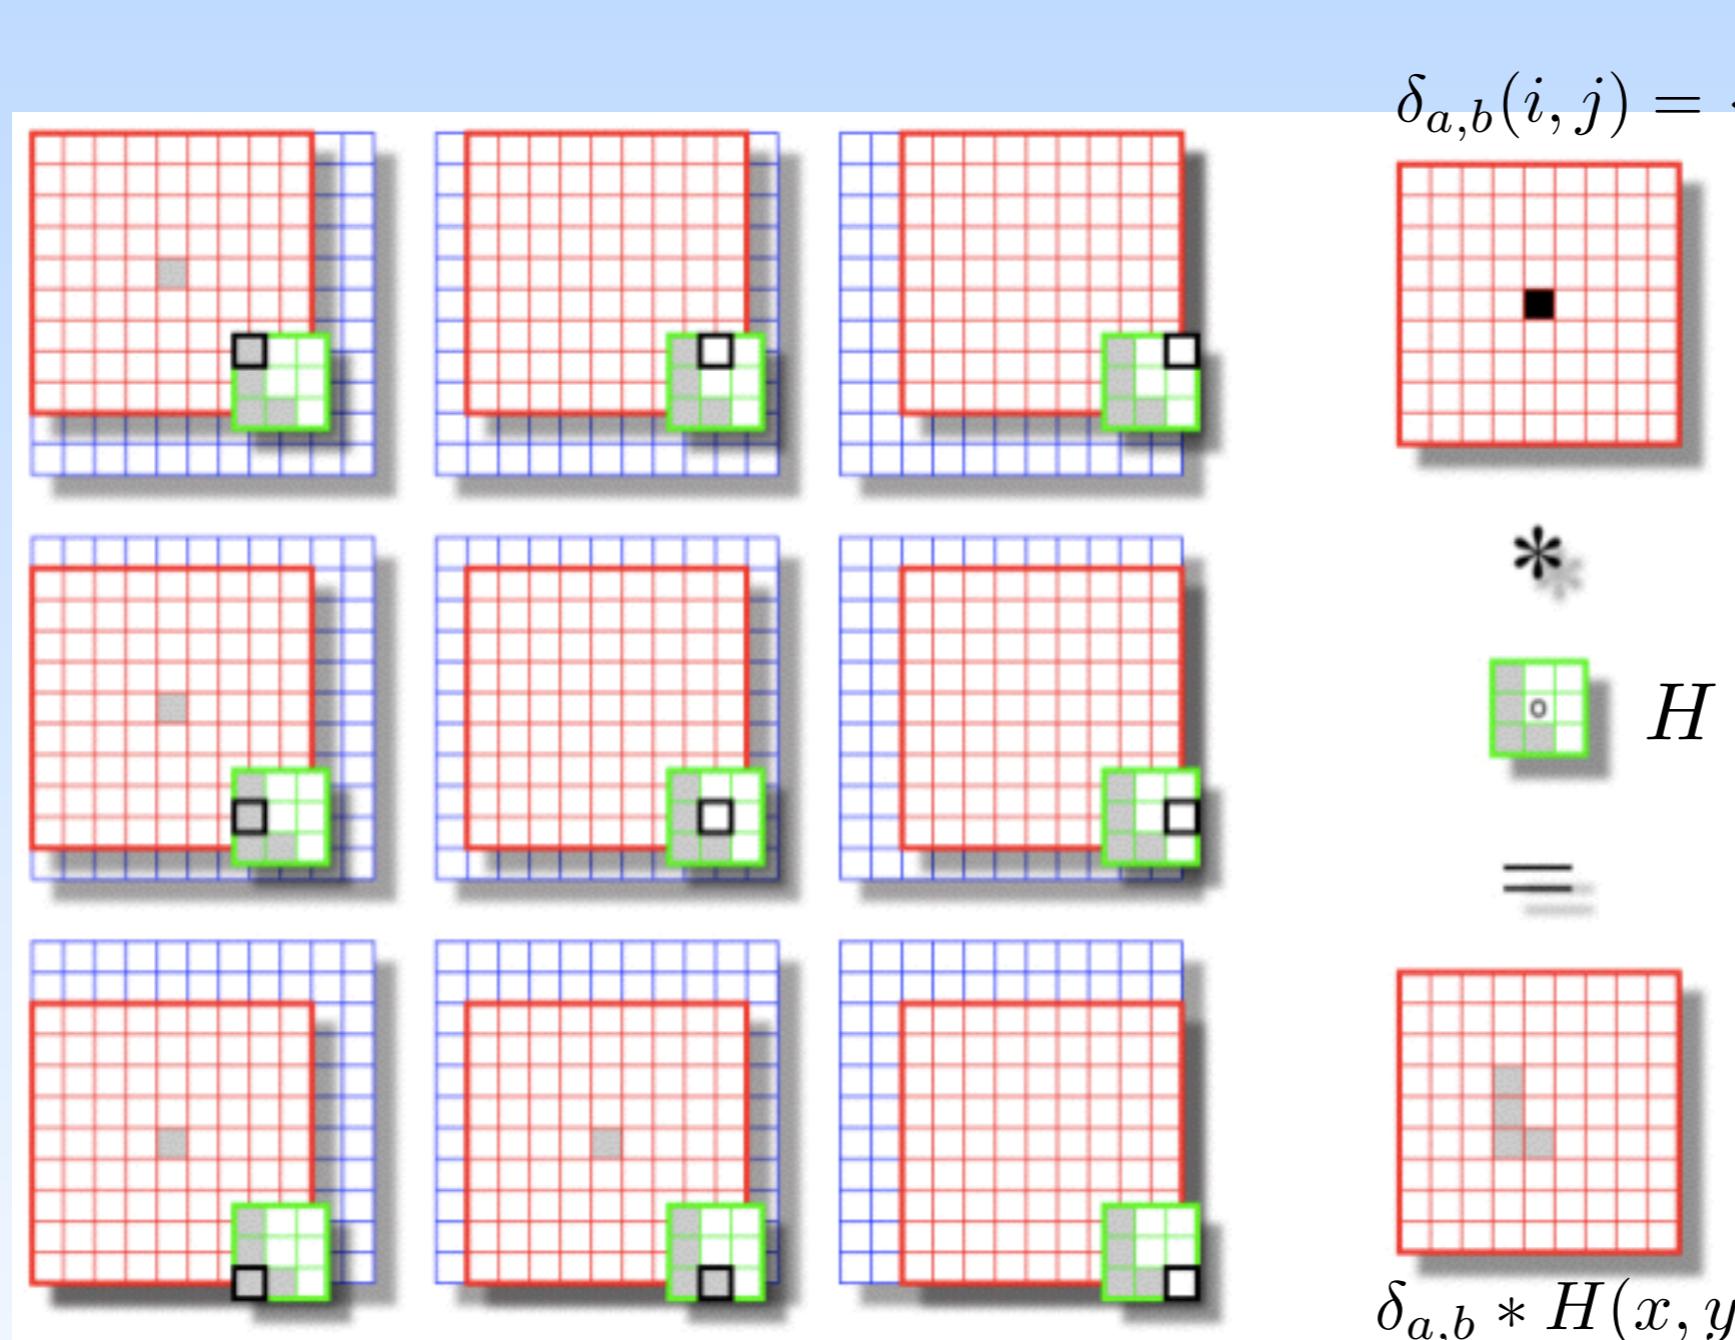

# Convolution by shifting, copying and multiplying the image

For each element  $H(i,j)$  in the kernel matrix, image  $I$  is copied into a zero-padded image,  $P$  starting at  $(i,j)$ . Each  $P$  is multiplied by the corresponding weight  $H(i,j)$ . All the  $P$  images are summed pixel-wise, then divided by the sum of the elements of  $h$ . The result is copied out of the center of the accumulated  $P$ 's.

$$J(x, y) = H * I = \sum_{i=-\infty}^{+\infty} \sum_{j=-\infty}^{+\infty} H(x - i, y - j)I(i, j)$$

# Shift invariance

The kernel(point spread function)  $H$  is shift invariant or space-invariant because the entries in  $H$  do not depend on the position  $(x, y)$  in the output image and the same operation is performed at each location in the image.

# Convolution properties

---

Commutativity

$$H * I = I * H$$

Associativity

$$H * (G * I) = (H * G) * I$$

In correlation

$$H \circ (G \circ I) \neq (H \circ G) \circ I$$

Distributivity

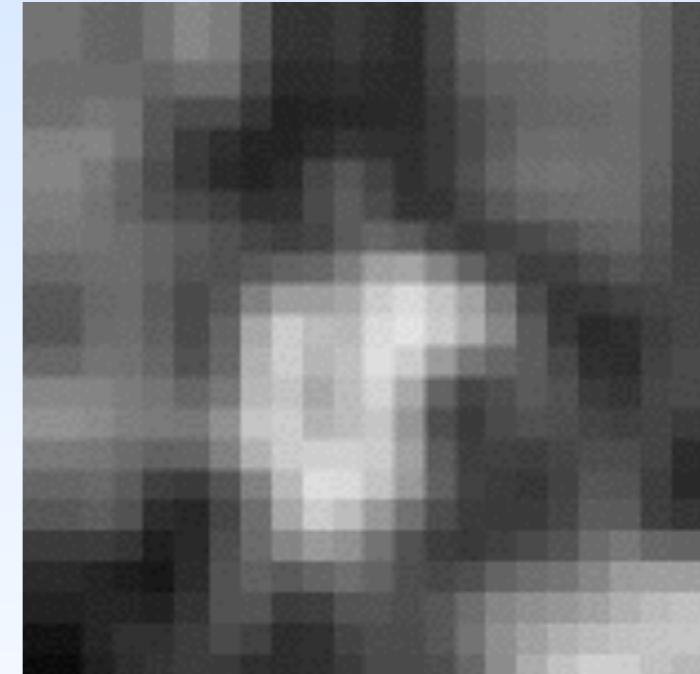

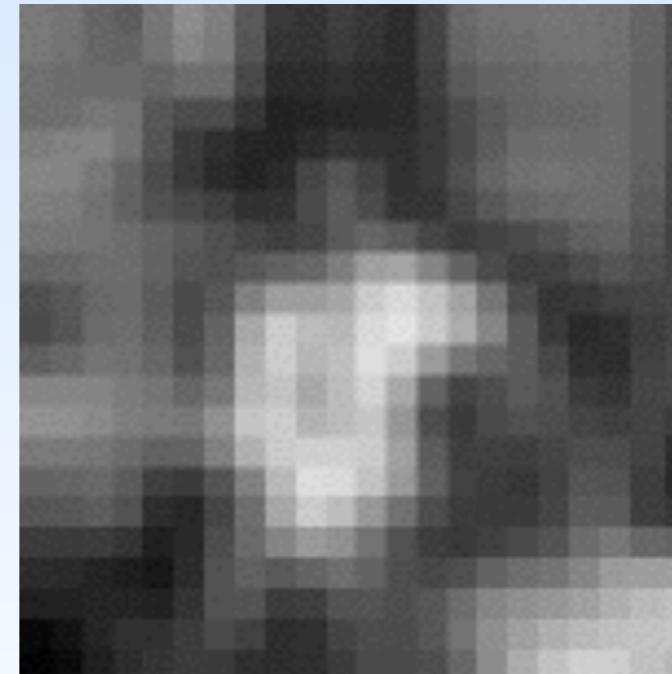

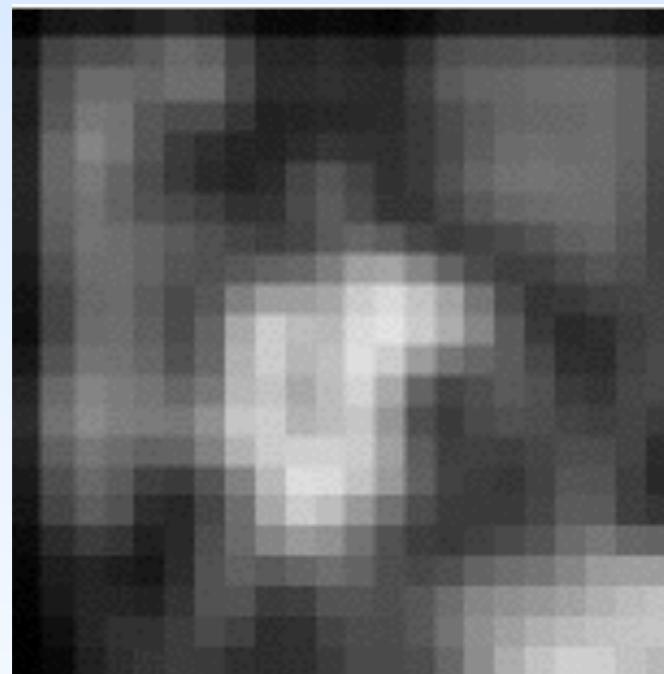

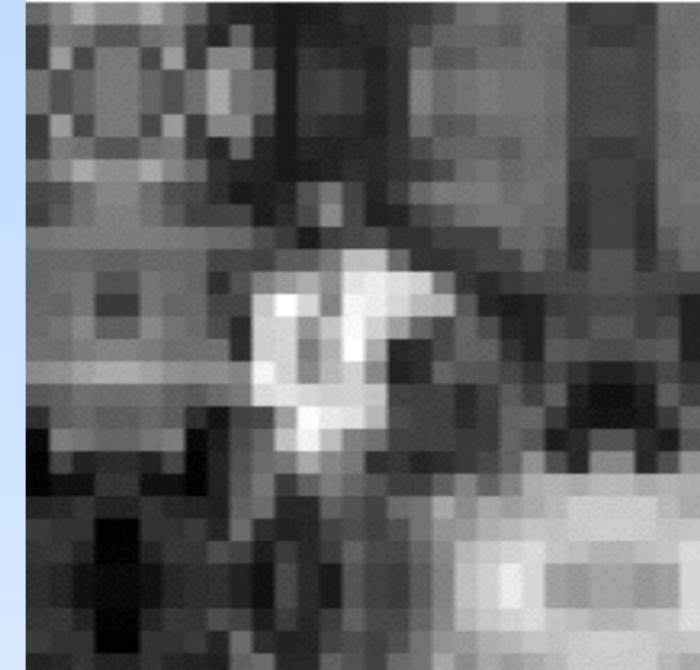

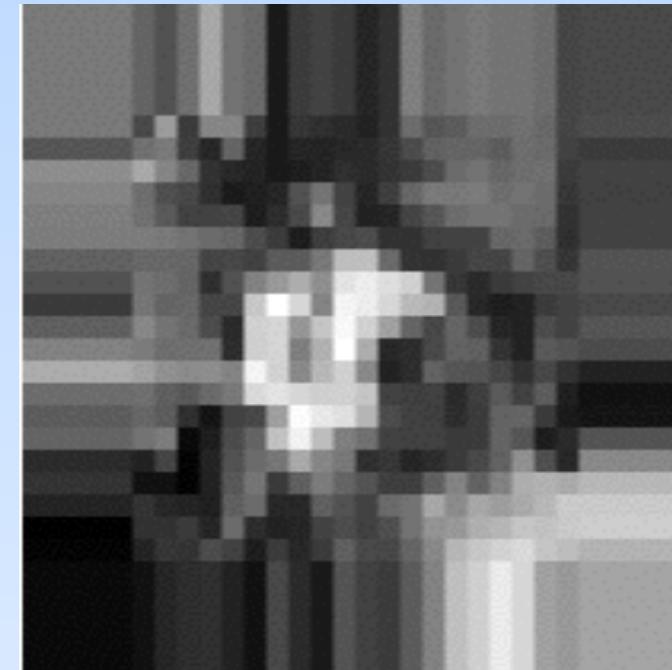

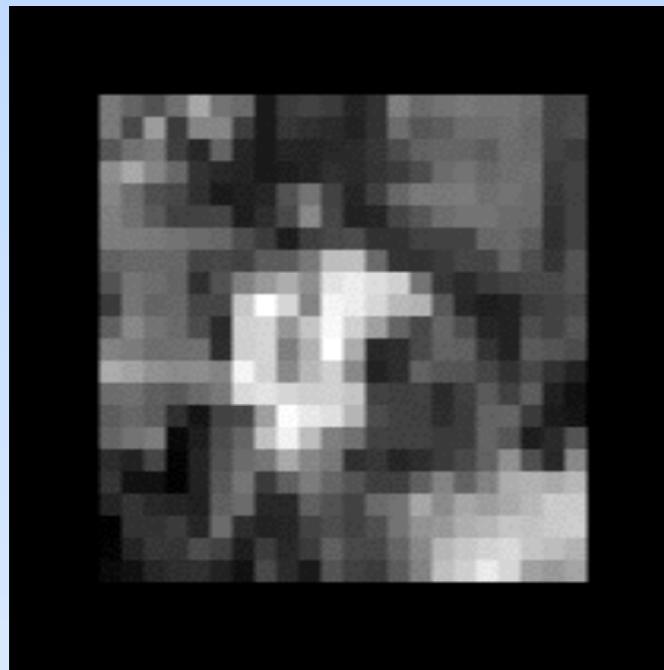

$$H * (I + J) = (H * I) + (H * J)$$

Associativity with scalar multiplication

$$a(H * I) = (aH) * I = H * (aI)$$

# Padding (border effects)

---

zero

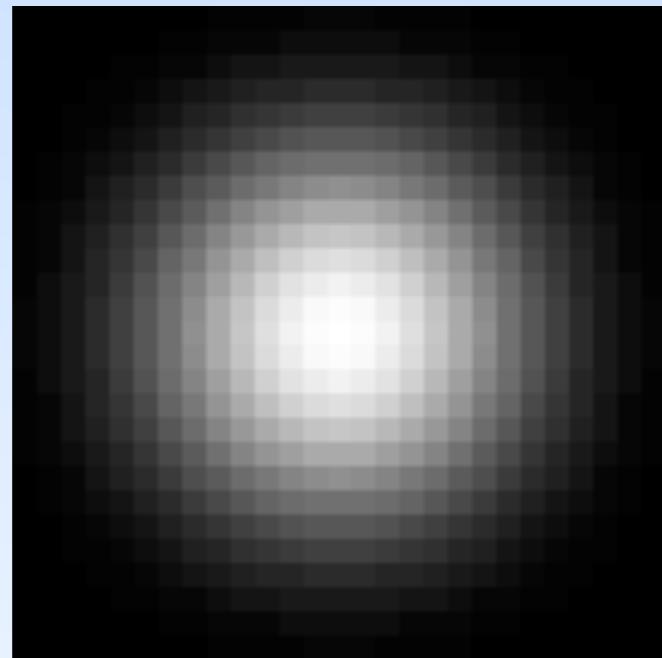

clamp

mirror

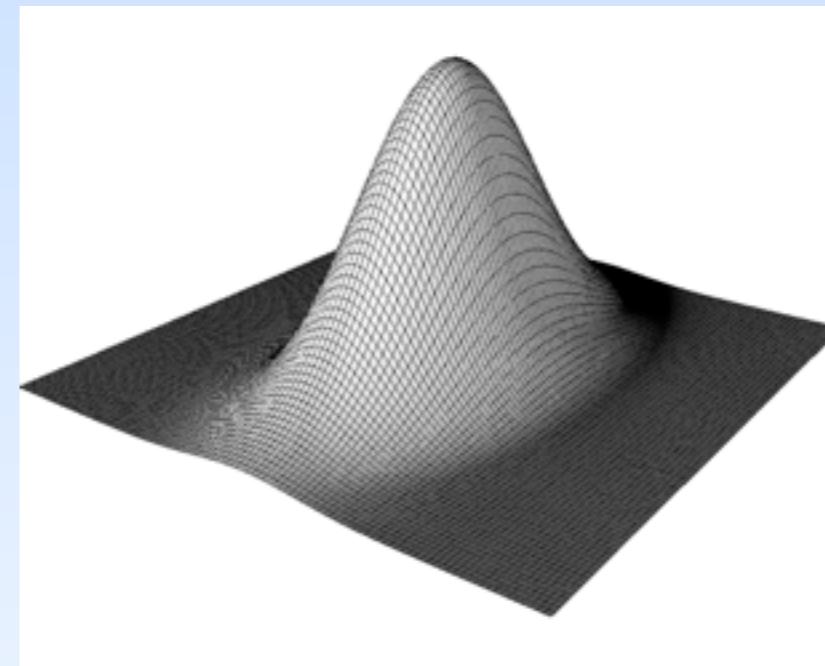

# Gaussian smoothing

---

$$G(u, v) = e^{-\frac{1}{2} \frac{u^2 + v^2}{\sigma^2}}$$

Gaussian kernel

Gaussian function

# Gaussian smoothing example

---

Original  
image

Smoothed  
 $\sigma = 1$

Smoothed  
 $\sigma = 2$

Smoothed  
 $\sigma = 4$

# Separability of Gaussians

---

$$G(u, v) = g(u)g(v)$$

$$G(u, v) = e^{-\frac{1}{2} \frac{u^2 + v^2}{\sigma^2}} \implies G(u, v) = e^{-\frac{1}{2} \left(\frac{u}{\sigma}\right)^2} e^{-\frac{1}{2} \left(\frac{v}{\sigma}\right)^2}$$

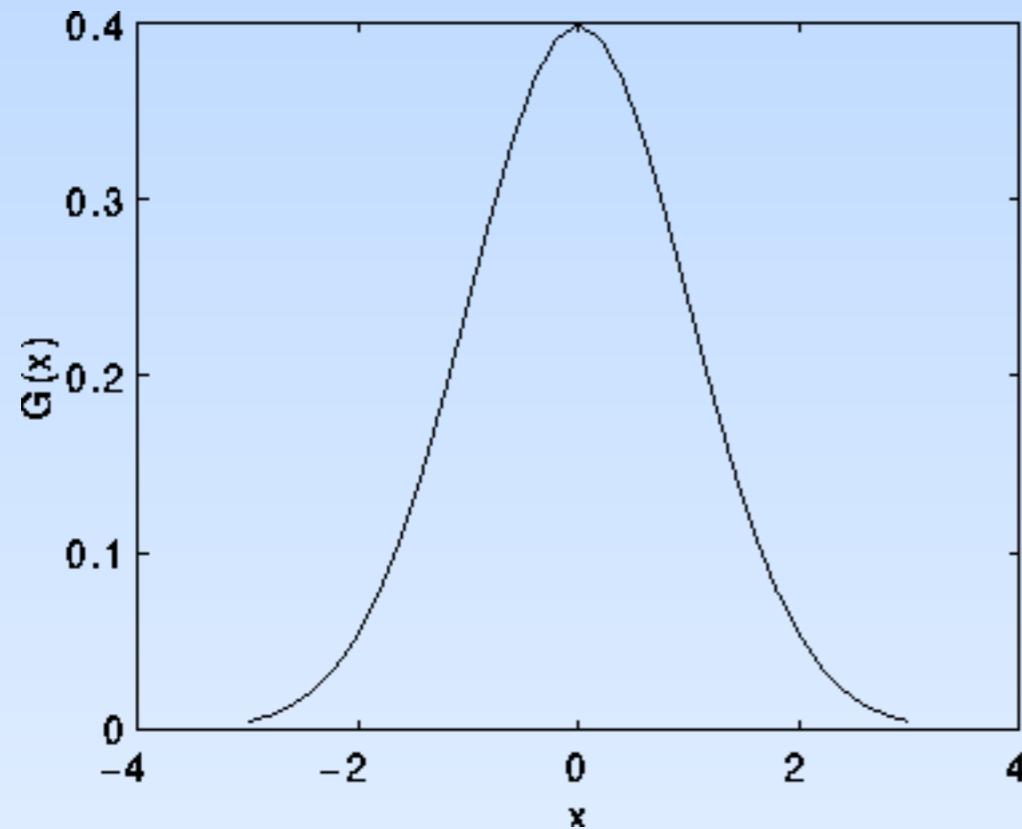

Gaussian separation speeds up computation, because with the separable kernel  $G$  the convolution can be separated in two one-dimensional convolutions like:

$$J(x, y) = \sum_{u=-n}^n g(u) \sum_{v=-n}^n g(v) I(x - u, y - v)$$

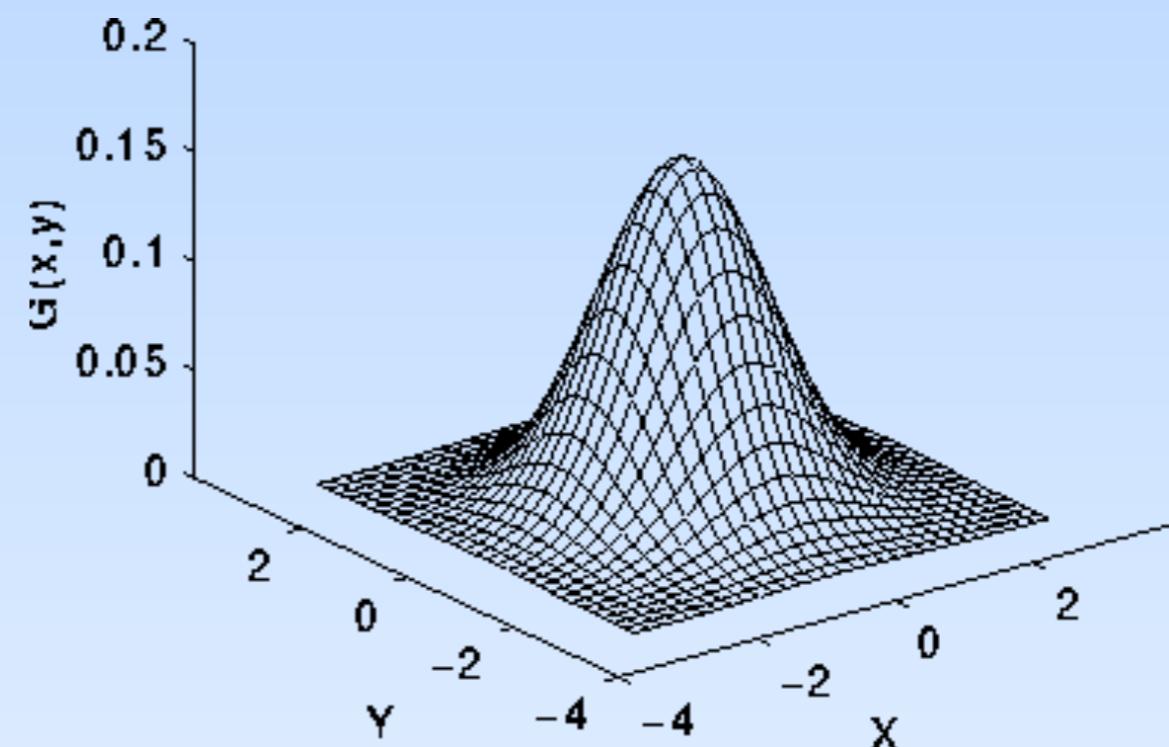

$$J(x, y) = \sum_{u=-n}^n g(u) \phi(x - u, y) \quad \phi(x, y) = \sum_{v=-n}^n g(v) I(x, y - v)$$

this requires  $2m$  multiplications and  $2(m-1)$  additions compared to  $m^2$  multiplications and  $m^2-1$  additions with 2D kernel, where  $m=2n+1$ .

# Gaussian normalization

$$G(x) = \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{1}{2} \frac{x^2}{\sigma^2}}$$

$$G(x, y) = \frac{1}{2\pi\sigma^2} e^{-\frac{1}{2} \frac{x^2+y^2}{\sigma^2}}$$

Since we discretize in practice we normalize not by the integral, but by the sum

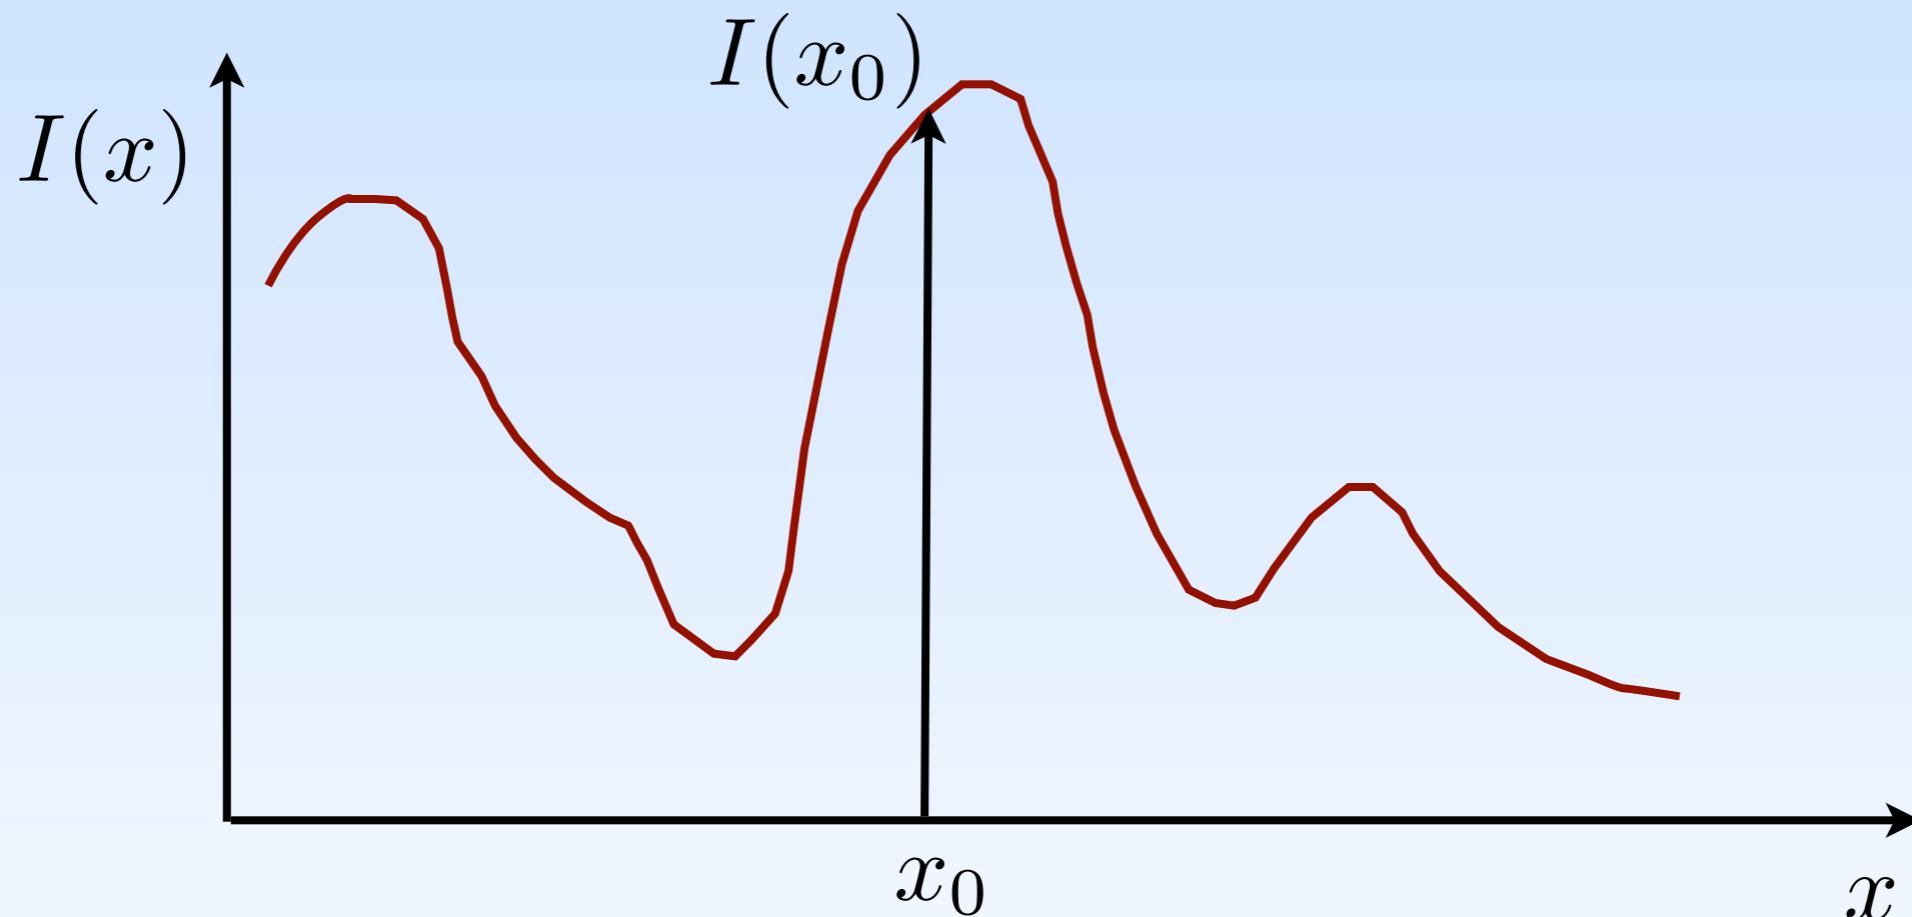

$$G(x, y) = \frac{1}{c} e^{-\frac{1}{2} \frac{x^2+y^2}{\sigma^2}}$$

$$c = \sum_{i=-n}^n \sum_{j=-n}^n G(i, j)$$

# Image derivatives

---

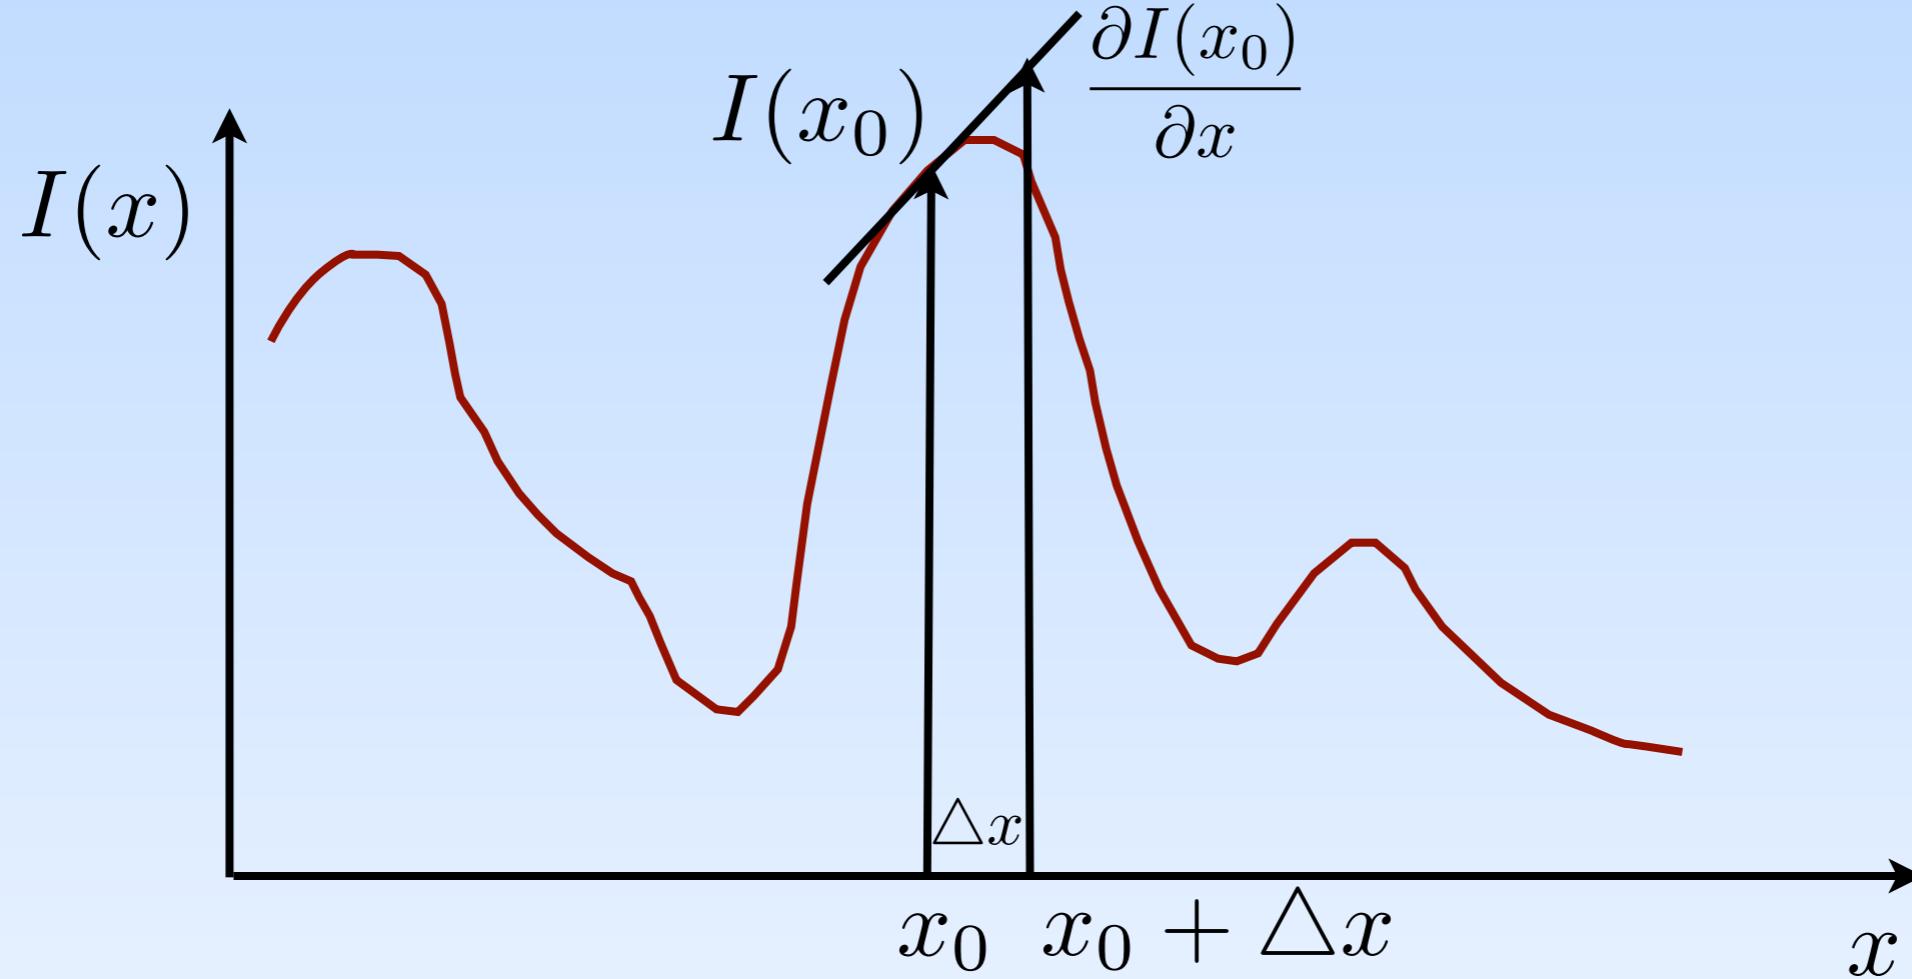

Remember that the image can be represented as a function of its pixel intensities

consequently we should be able to compute derivatives of this function ...

# Linear approximation

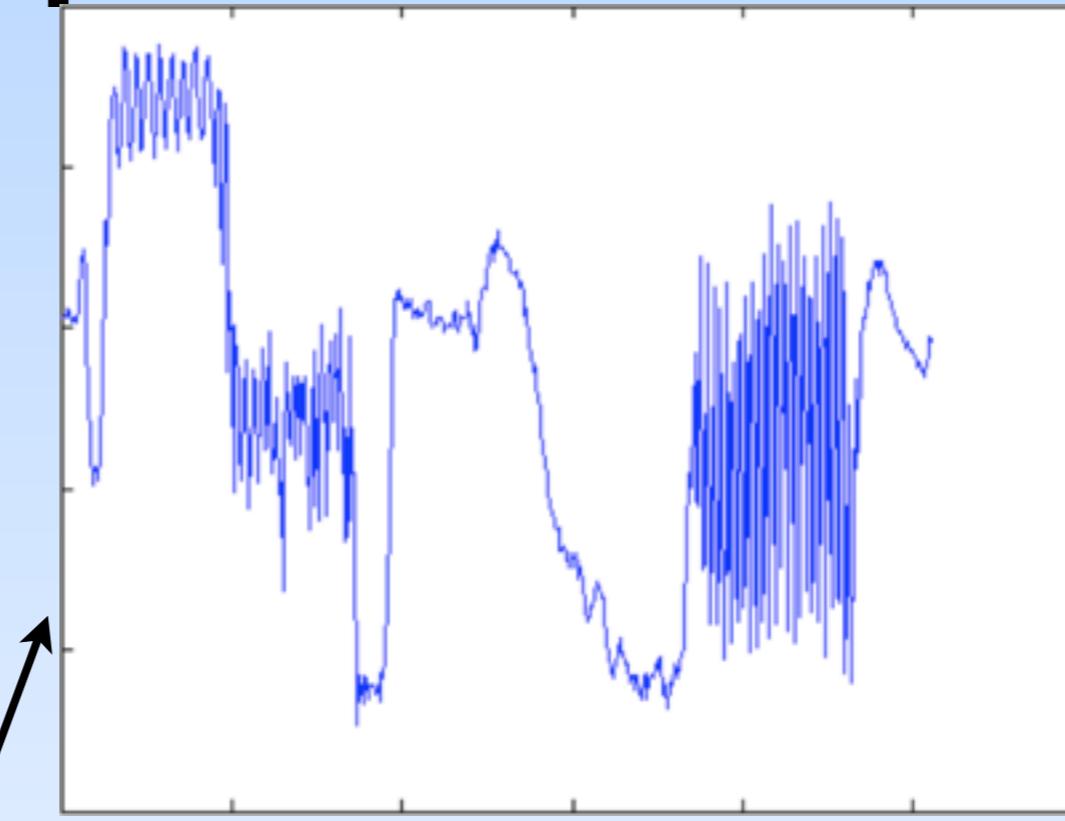

---

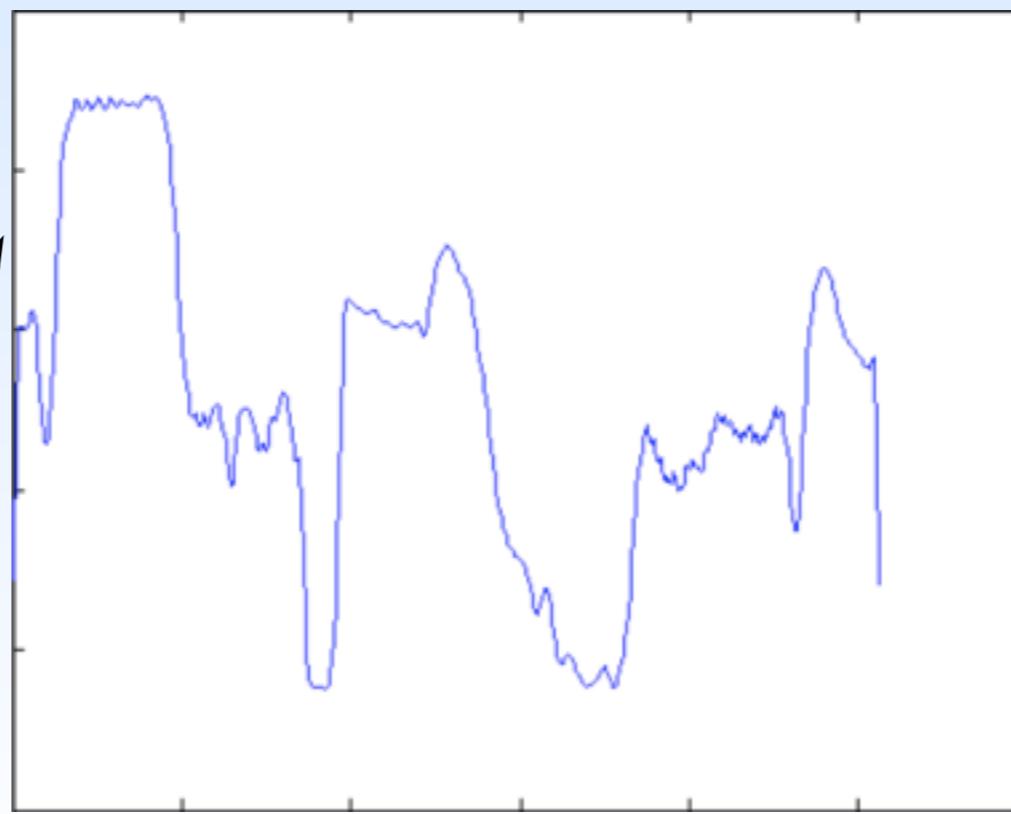

$$I(x_0 + \Delta x) \approx I(x_0) + \frac{\partial I(x_0)}{\partial x} \Delta x + h.o.t$$

$$\frac{\partial I(x_0)}{\partial x} = \lim_{\Delta x \rightarrow 0} \frac{I(x_0 + \Delta x) - I(x_0)}{\Delta x} \approx I(x_0 + \Delta x) - I(x_0)$$

# Image ID profile example

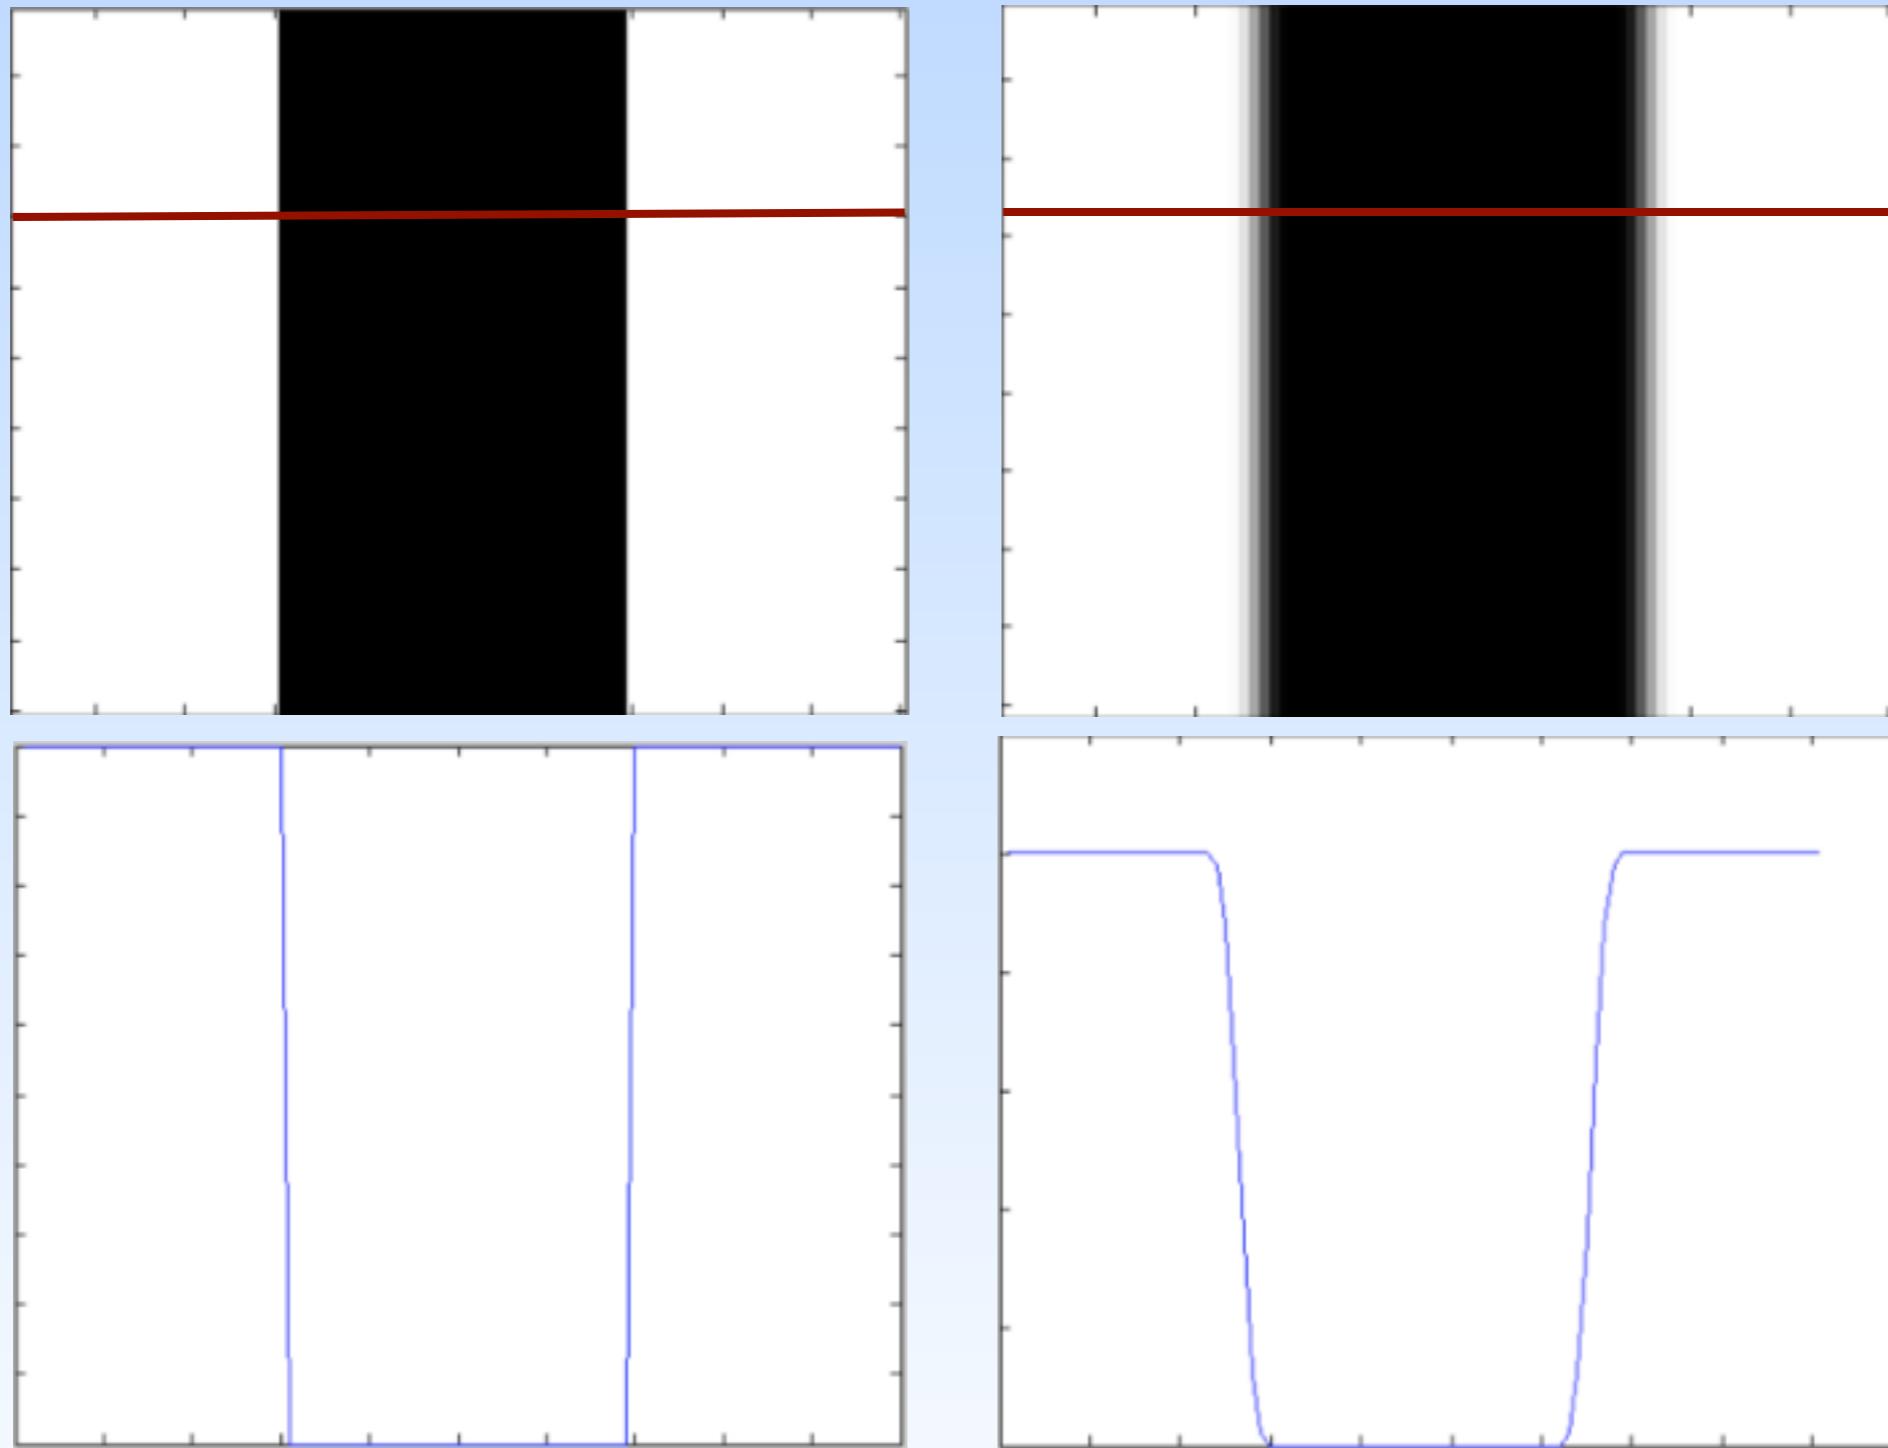

ID image  
line profile

ID image  
line profile  
smoothed  
with  
Gaussian

# Example images

---

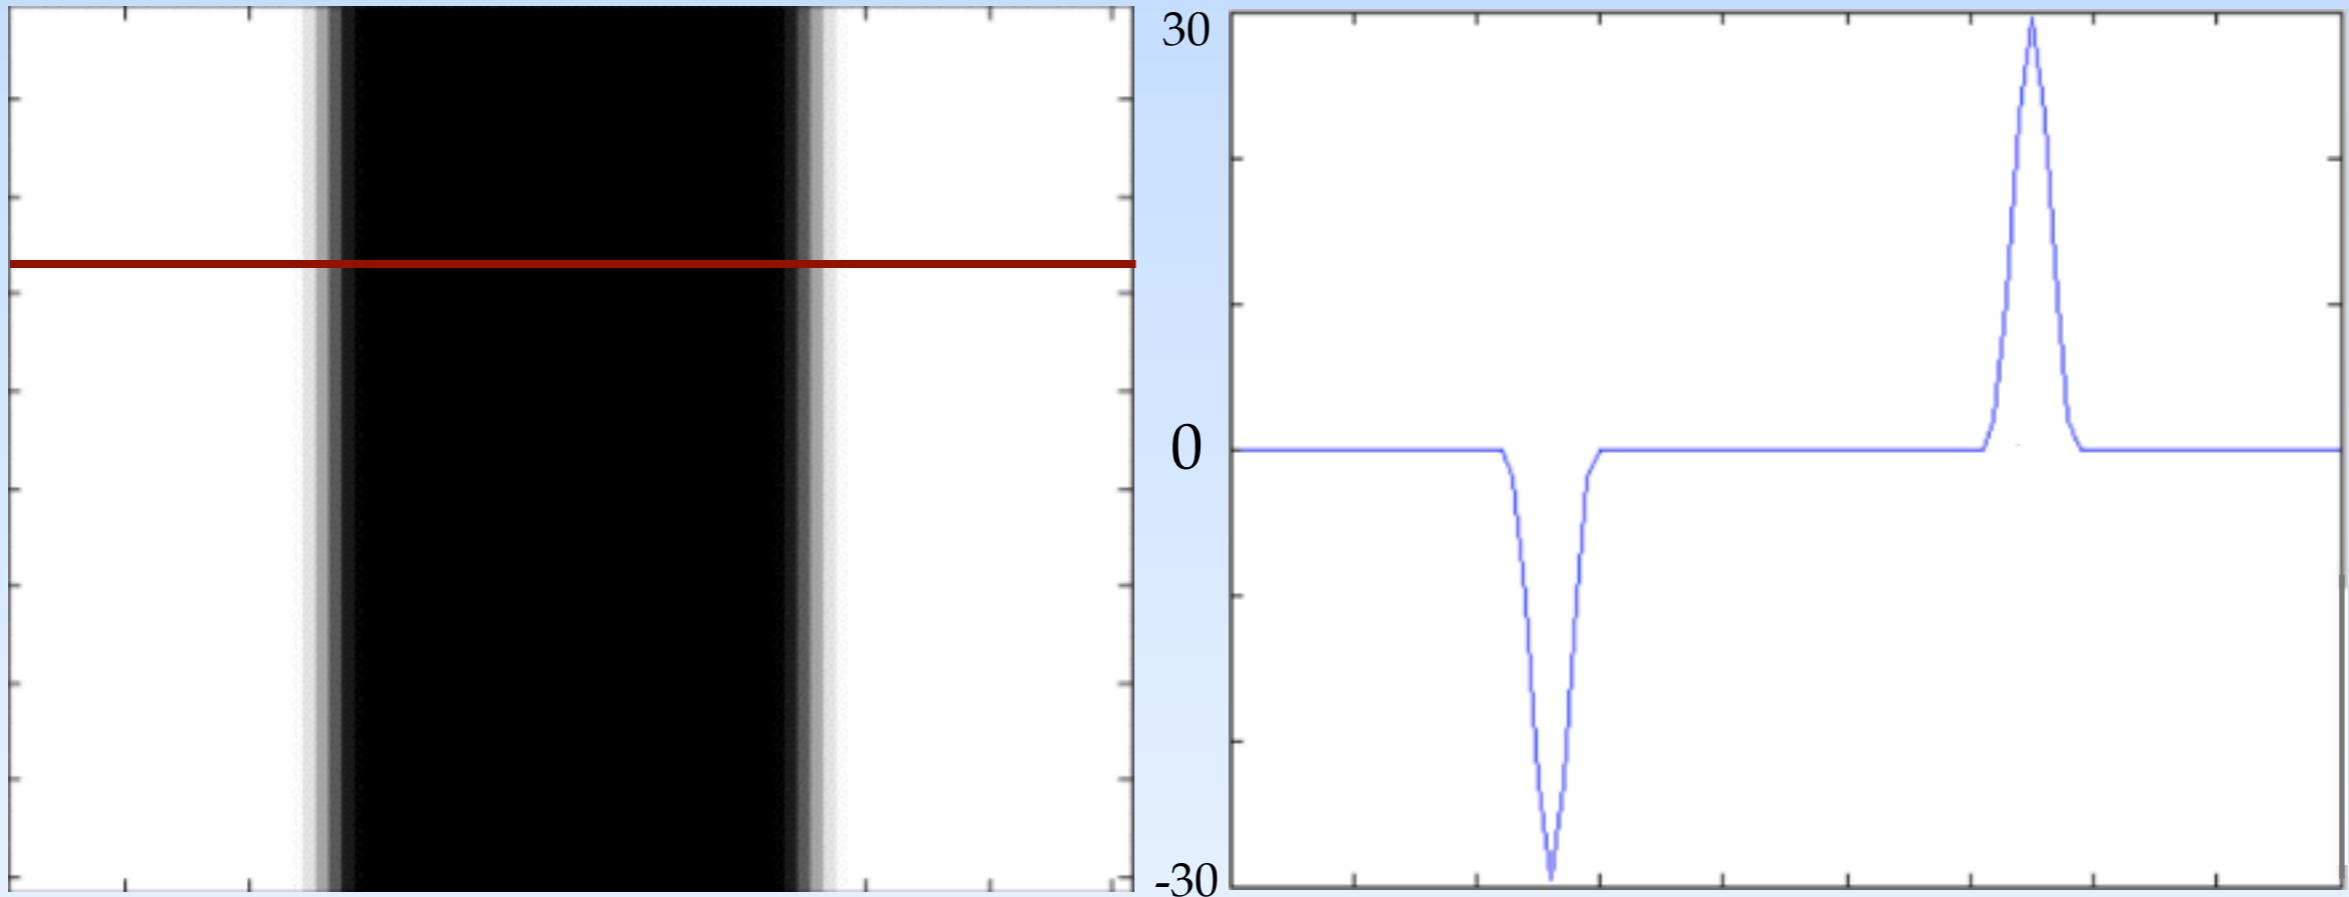

Discontinuity

Smoothed with  
Gaussian

# Example images derivatives

---

Edges correspond to the fast changes in the intensities

Magnitude of the derivatives is large

# Derivatives as linear filters

---

Image derivative:

$$\frac{\partial I(x_0)}{\partial x} = \lim_{\Delta x \rightarrow 0} \frac{I(x_0 + \Delta x) - I(x_0)}{\Delta x} \approx I(x_0 + \Delta x) - I(x_0)$$

can be implemented as linear filters:

Convolution:

$$H * I = [1 \ -1] * I$$

Matrix multiplication:

$$H \cdot I = [-1 \ 1] \cdot [I(x_0) \ I(x_0 + \Delta x)]^T$$

or in its symmetric version:

Convolution  $H * I = [1 \ 0 \ -1] * I$

Matrix mult.  $H \cdot I = [-1 \ 0 \ 1] \cdot [I(x_0 - \Delta x) \ I(x_0) \ I(x_0 + \Delta x)]^T$

# Partial image derivatives

---

If we consider an image  $I$  as a function of vector variables  $I(x, y)$  we write image gradient using partial derivatives as:

$$\nabla I(x, y) = \frac{\partial I}{\partial x} \vec{i}_x + \frac{\partial I}{\partial y} \vec{i}_y$$

This can be written using gradient filters:

$$\nabla I(x, y) = (D_x * I) \vec{i}_x + (D_y * I) \vec{i}_y$$

And we can define gradient intensity and direction:

$$|\nabla I(x, y)| = \sqrt{(D_x * I)^2 + (D_y * I)^2} \quad \psi(\nabla I) = \arctan \left( \frac{D_y * I}{D_x * I} \right)$$

# Gradient filters

---

Basic derivative filters:

$$D_x = \begin{bmatrix} 1 & 0 & -1 \\ 1 & 0 & -1 \\ 1 & 0 & -1 \end{bmatrix}$$

$$D_y = \begin{bmatrix} 1 & 1 & 1 \\ 0 & 0 & 0 \\ -1 & -1 & -1 \end{bmatrix}$$

Prewitt gradient filter

$$D_x = \frac{1}{3} \begin{bmatrix} 1 & 0 & -1 \\ 1 & 0 & -1 \\ 1 & 0 & -1 \end{bmatrix}$$

$$D_y = \frac{1}{3} \begin{bmatrix} 1 & 1 & 1 \\ 0 & 0 & 0 \\ -1 & -1 & 1 \end{bmatrix}$$

Sobel gradient filter

$$D_x = \frac{1}{4} \begin{bmatrix} 1 & 0 & -1 \\ 2 & 0 & -2 \\ 1 & 0 & -1 \end{bmatrix}$$

$$D_y = \frac{1}{4} \begin{bmatrix} 1 & 2 & 1 \\ 0 & 0 & 0 \\ -1 & -2 & -1 \end{bmatrix}$$

# Gradients smoothed with Gaussians

---

Images smoothed with Gaussians and then filtered with derivatives filters:

$$I_x = D_x * (G * I) \quad I_y = D_y * (G * I)$$

Because of the associativity:

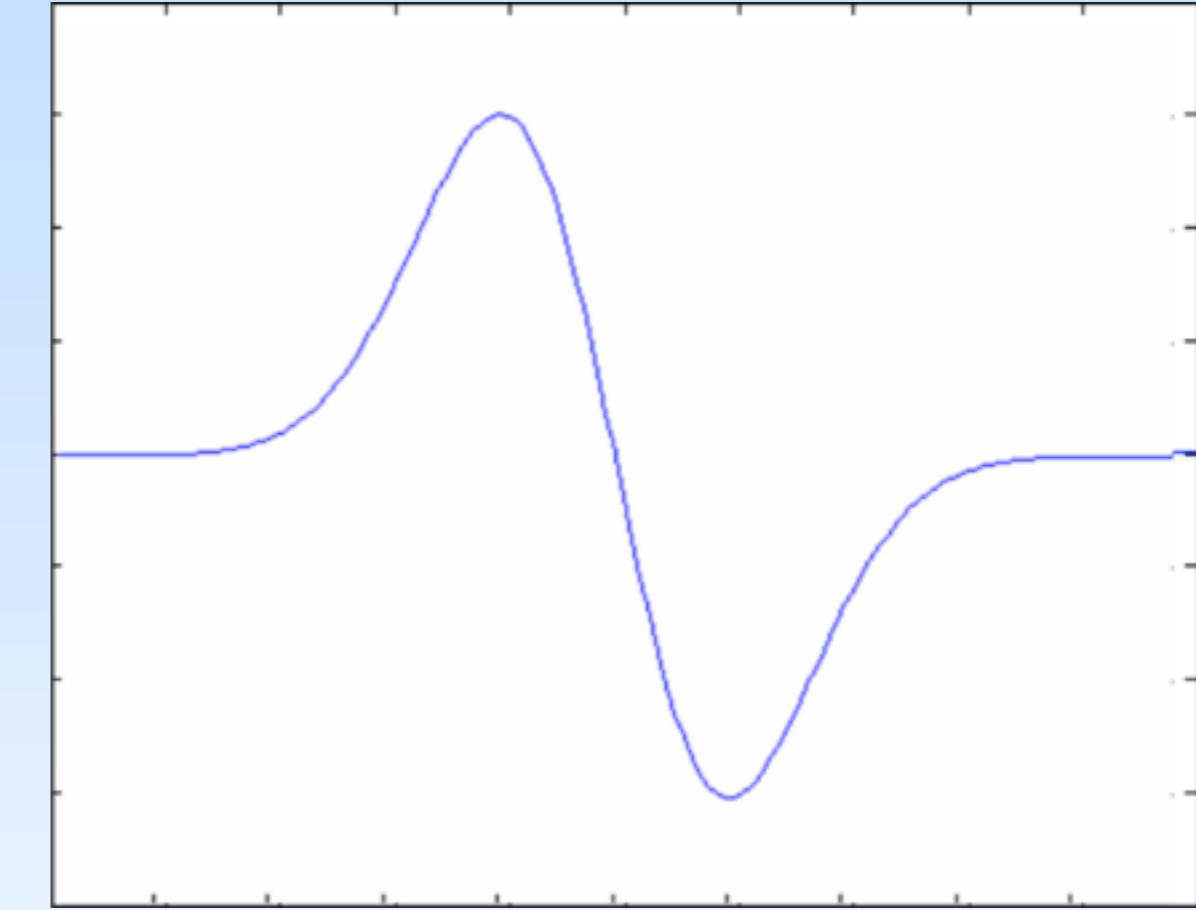

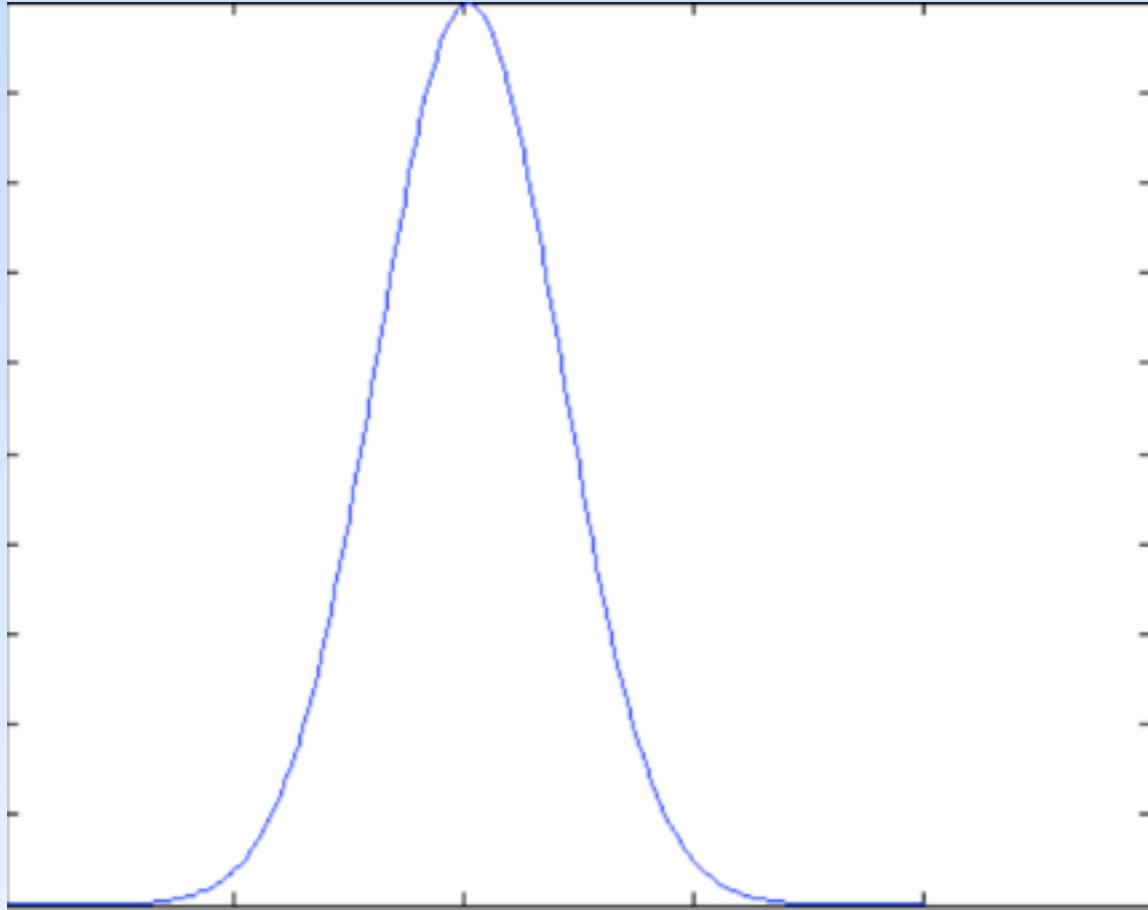

**Cannot be done with correlation**

$$I_x = (D_x * G) * I = G_x * I \quad I_y = (D_y * G) * I = G_y * I$$

images can be directly convolved by the derivatives of the Gaussian filters.

# Derivatives of Gaussians in 1D

---

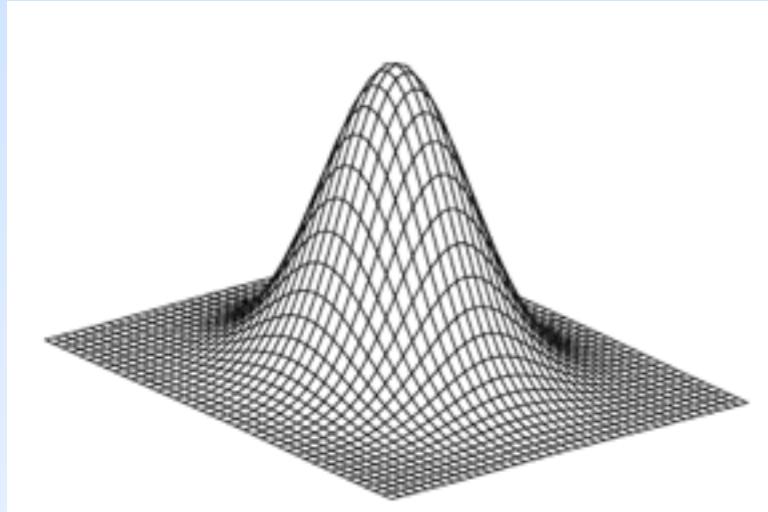

$$G(x) = \frac{1}{\sigma\sqrt{2\pi}}e^{-\frac{1}{2}\frac{x^2}{\sigma^2}}$$

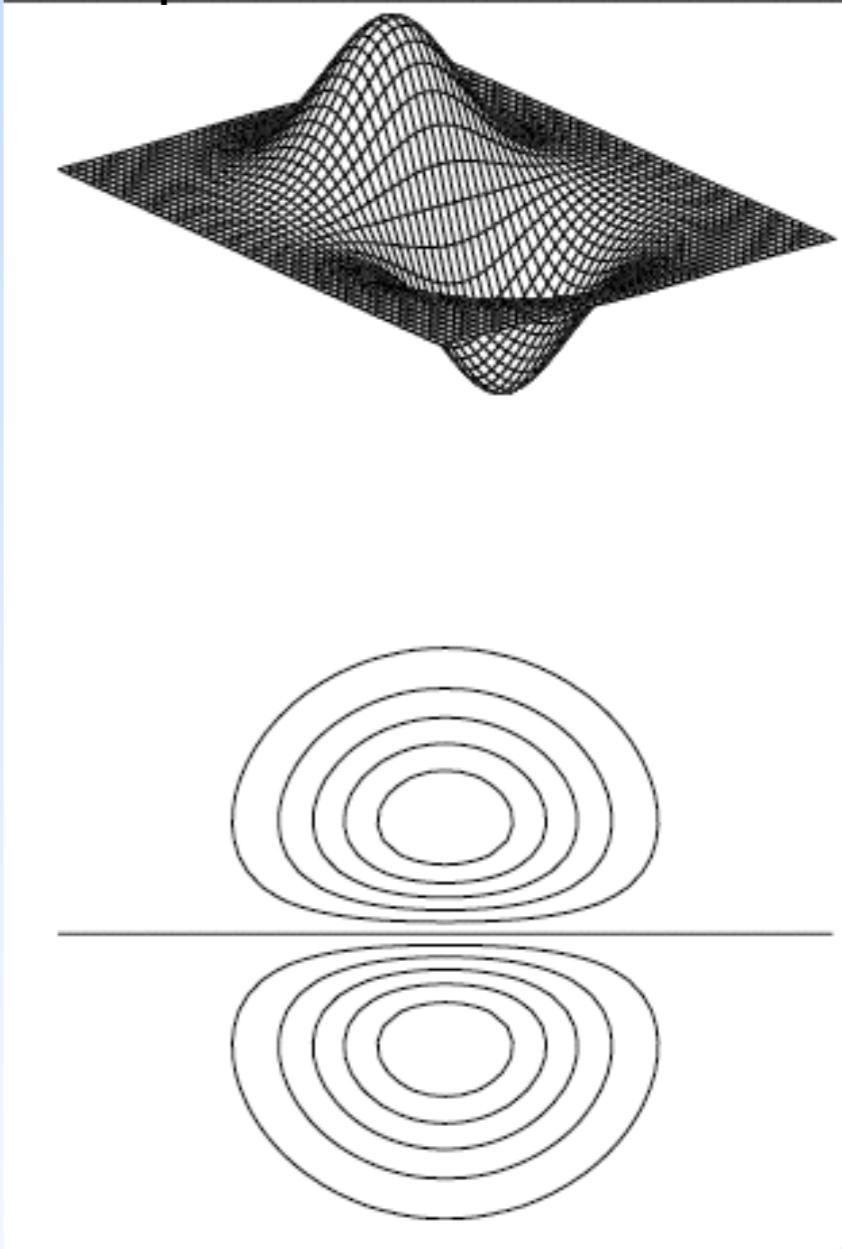

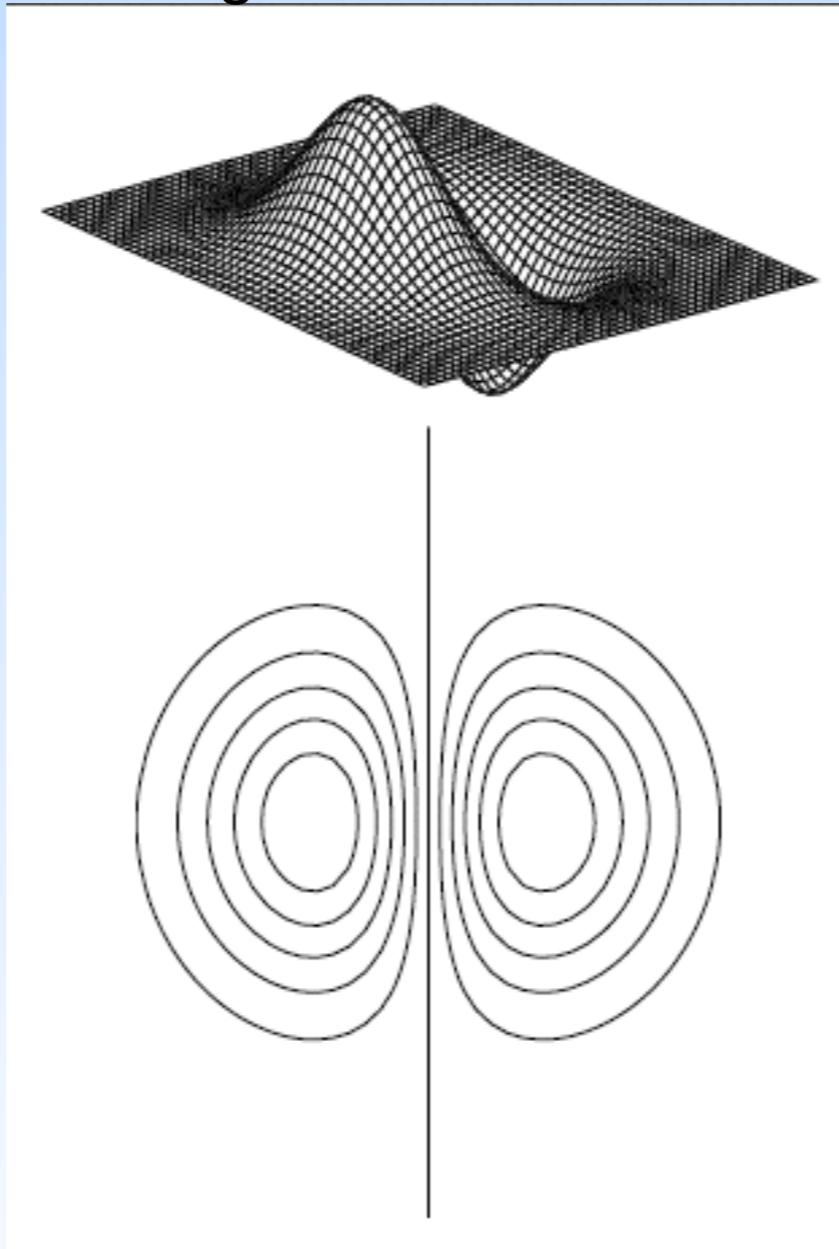

$$G_x = \frac{\partial G}{\partial x} = -\frac{x}{\sigma^3\sqrt{2\pi}}e^{-\frac{x^2}{2\sigma^2}}$$

# Derivatives of Gaussians in 2D

Images are from Carlo Tomasi Computer Vision lecture notes

$$G(x, y) = \frac{1}{2\pi\sigma^2} e^{-\frac{1}{2} \frac{x^2+y^2}{\sigma^2}}$$

$$G_x = \frac{\partial G}{\partial x} = \frac{-x}{2\pi\sigma^4} e^{-\frac{1}{2} \frac{x^2+y^2}{\sigma^2}}$$

$$G_y = \frac{\partial G}{\partial y} = \frac{-y}{2\pi\sigma^4} e^{-\frac{1}{2} \frac{x^2+y^2}{\sigma^2}}$$

# Practical Aspects and normalization

---

Derivatives without normalization and due to separability:

$$G_x(x, y) = -\frac{x}{\sigma^2} e^{-\frac{1}{2} \frac{x^2+y^2}{\sigma^2}} = G_x(x)G(y)$$

$$G_y(x, y) = -\frac{y}{\sigma^2} e^{-\frac{1}{2} \frac{x^2+y^2}{\sigma^2}} = G_y(y)G(x)$$

in discreet case:

$$\begin{aligned} I_x(x, y) &= \sum_{i=-n}^n \sum_{j=-n}^n I(i, j)G_x(x - i, y - j) = \\ &= \sum_{i=-n}^n G_x(x - i) \sum_{j=-n}^n I(i, j)G(y - j) = \sum_{j=-n}^n G(y - j) \sum_{i=-n}^n I(i, j)G_x(x - i) \\ I_y(x, y) &= \sum_{i=-n}^n \sum_{j=-n}^n I(i, j)G_y(x - i, y - j) = \\ &= \sum_{i=-n}^n G(x - i) \sum_{j=-n}^n I(i, j)G_y(y - j) = \sum_{j=-n}^n G_y(y - j) \sum_{i=-n}^n I(i, j)G(x - i) \end{aligned}$$

---

# With normalization

---

$$I_x(x, y) = \sum_{i=-n}^n \overline{G}_x(x - i) \sum_{j=-n}^n I(i, j) \overline{G}(y - j)$$
$$I_y(x, y) = \sum_{i=-n}^n \overline{G}(x - i) \sum_{j=-n}^n I(i, j) \overline{G}_y(y - j)$$

Normalize by the sum of the filter samples:

$$\overline{G}_u(u) = k_g * G_u(u), \quad \text{where } G_u(u) = -ue^{-\frac{1}{2}\left(\frac{u}{\sigma}\right)^2} \quad \text{and} \quad k_d = \frac{1}{\sum_{u=-n}^n u G_u(u)}$$

$$\overline{G}(u) = k * G(u), \quad \text{where } G(u) = e^{-\frac{1}{2}\left(\frac{u}{\sigma}\right)^2} \quad \text{and} \quad k = \frac{1}{\sum_{u=-n}^n G_u(u)}$$

# Image directional gradients

---

Gradient in x direction  $G_x$

Gradient in y direction  $G_y$

# Gradient magnitude

---

$$|\nabla I(x, y)| = \sqrt{(G_x * I)^2 + (G_y * I)^2}$$

$\sigma = 0.5$

$\sigma = 1.0$

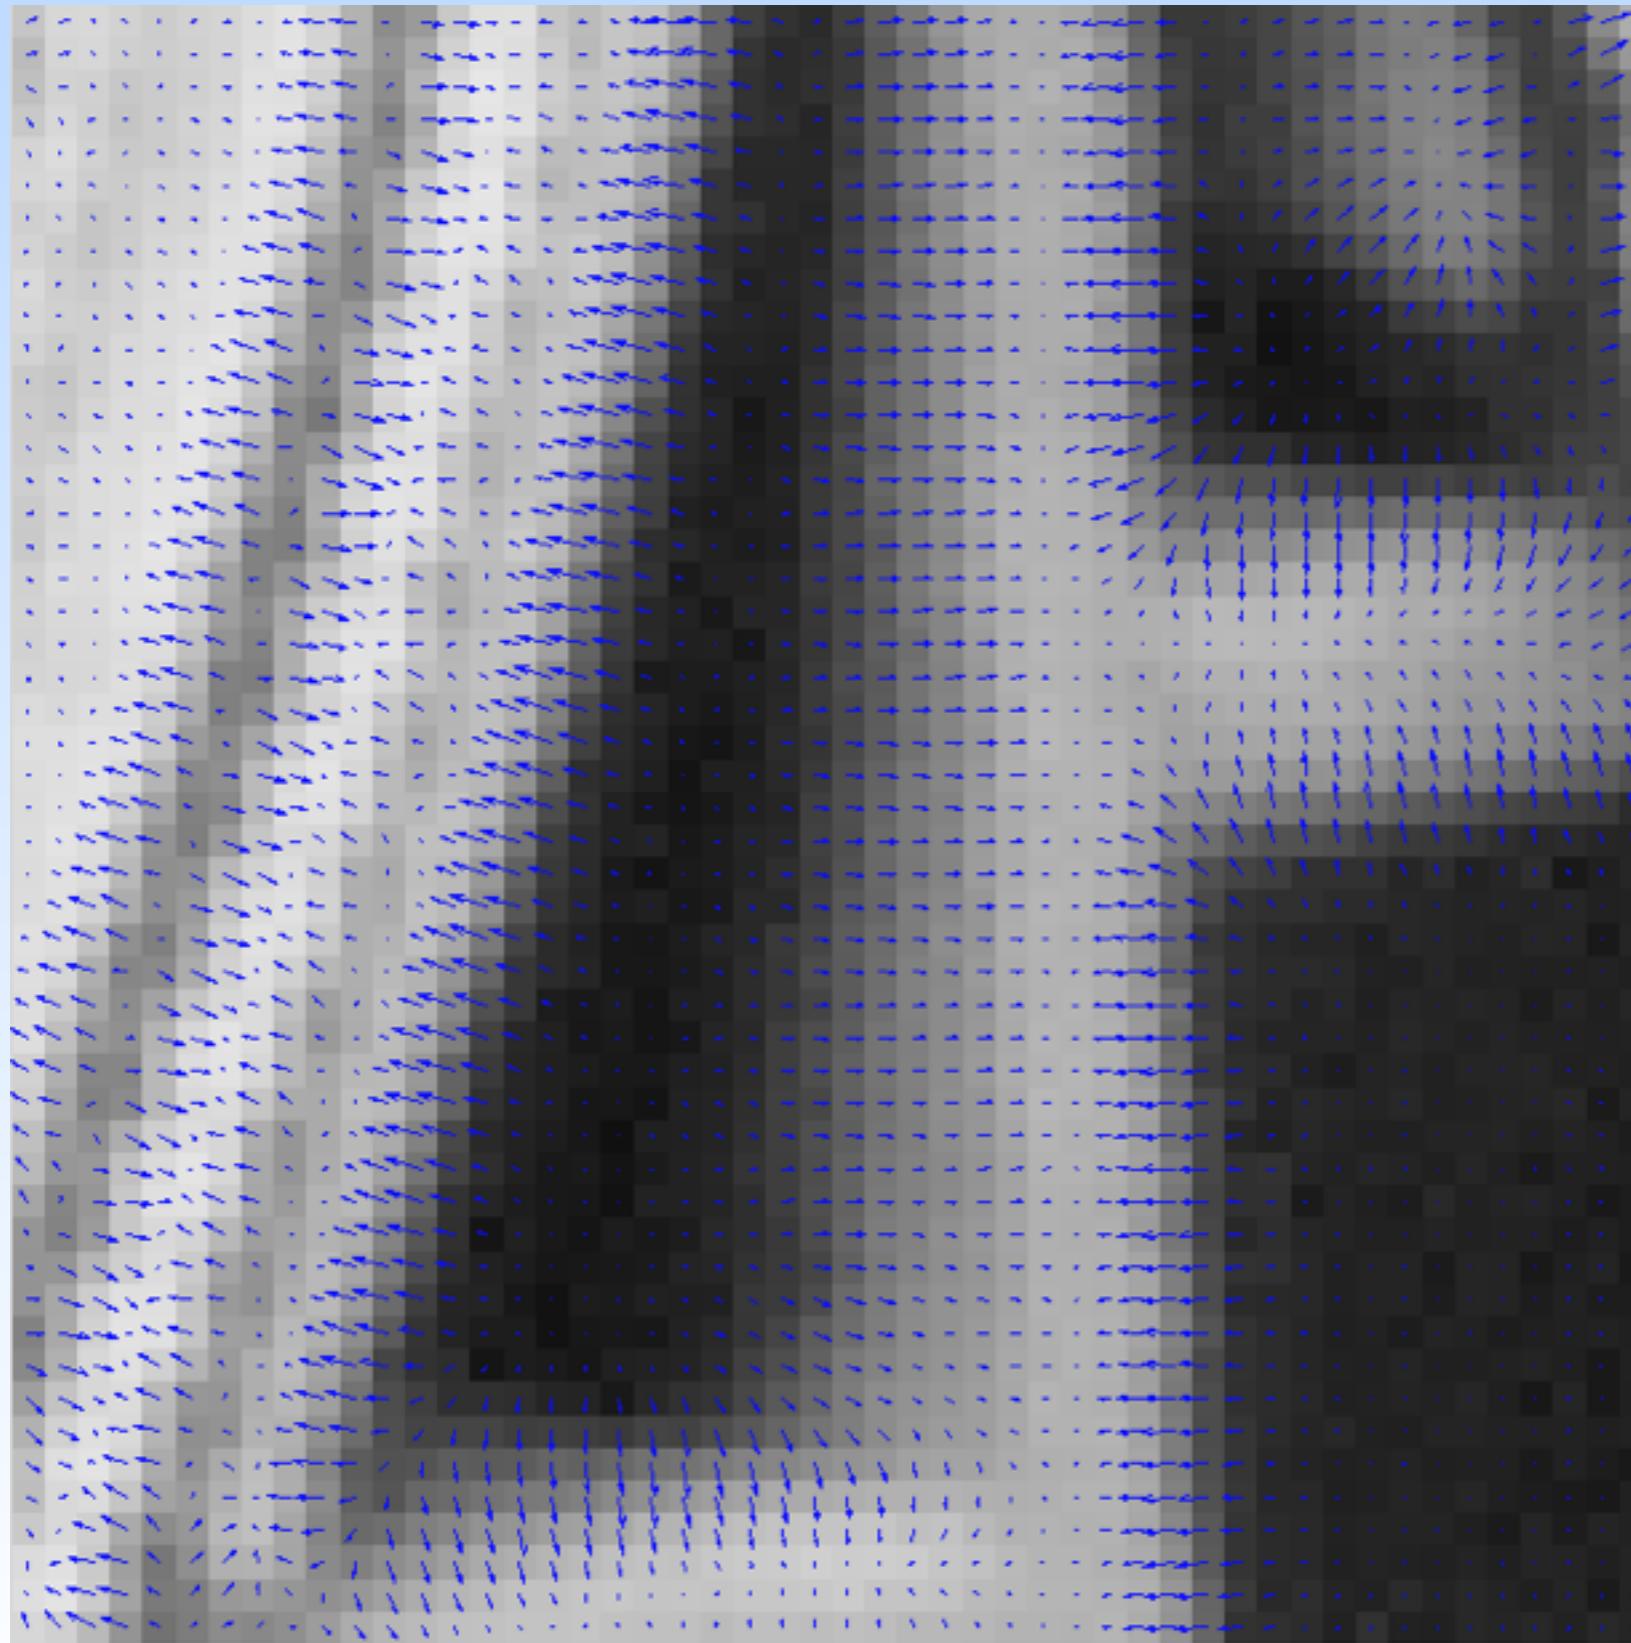

$\sigma = 1.5$

$\sigma = 2.0$

# Gradient orientation

The upper left corner of the image of 50x50 pixels large.

Gradient orientation computed as:

$$\psi(\nabla I) = \arctan \left( \frac{G_x * I}{G_y * I} \right)$$

# Second order derivatives

---

Mathematically we have:

$$\frac{\partial^2 I(x_0)}{\partial x^2} = \lim_{\Delta x \rightarrow 0} \frac{I'(x_0 + \Delta x) - I'(x_0)}{\Delta x} \approx I'(x_0 + \Delta x) - I'(x_0)$$

Further simplified:

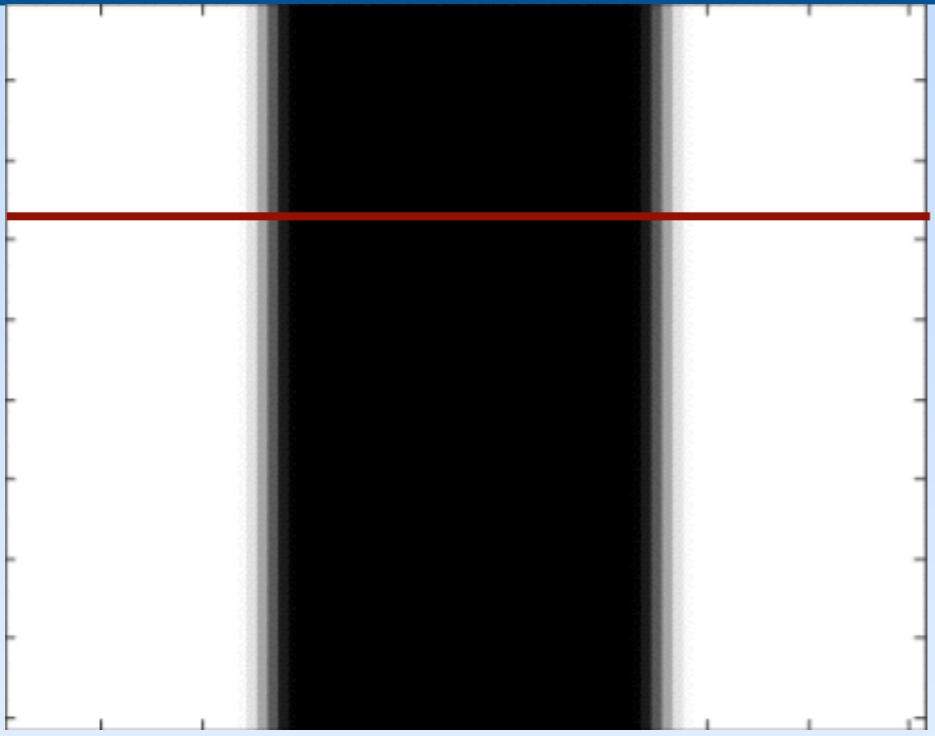

$$\frac{\partial^2 I(x_0)}{\partial x^2} = \nabla^2 I = I(x_0 + 2\Delta x) - 2I(x_0 + \Delta x) + I(x_0)$$

In 2D:

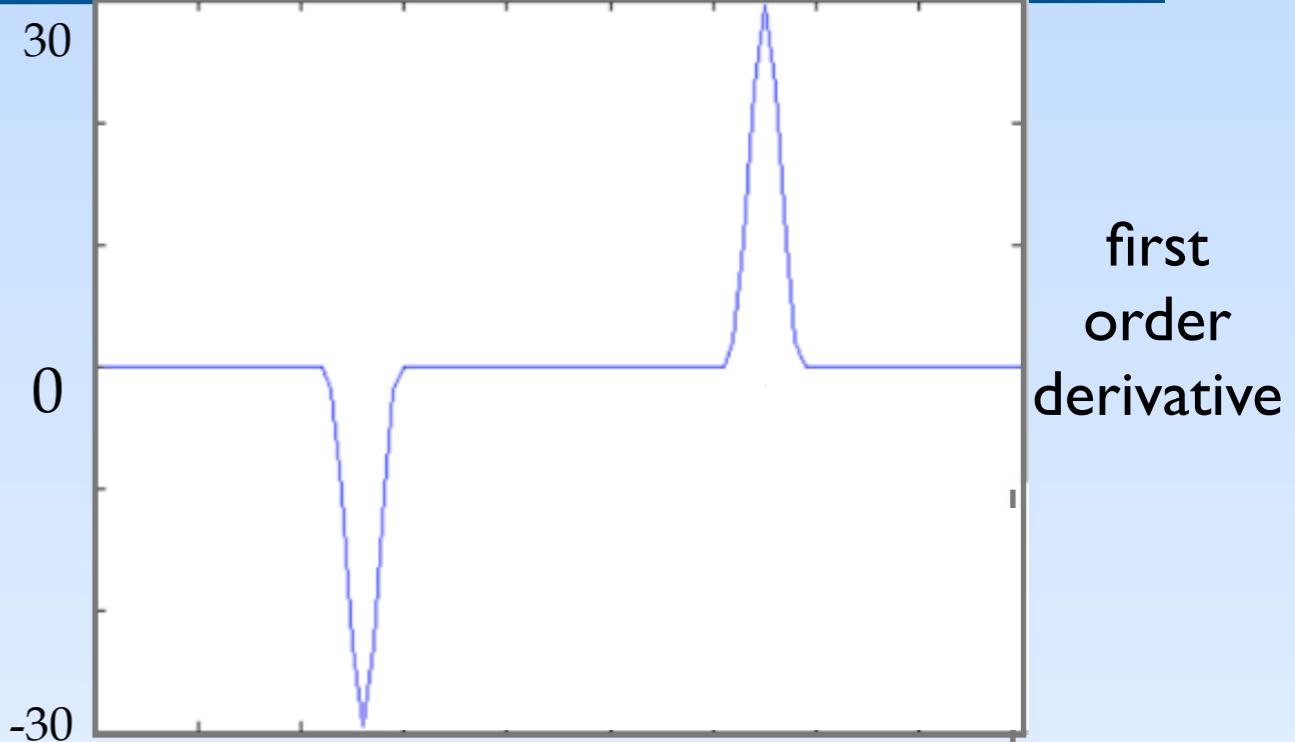

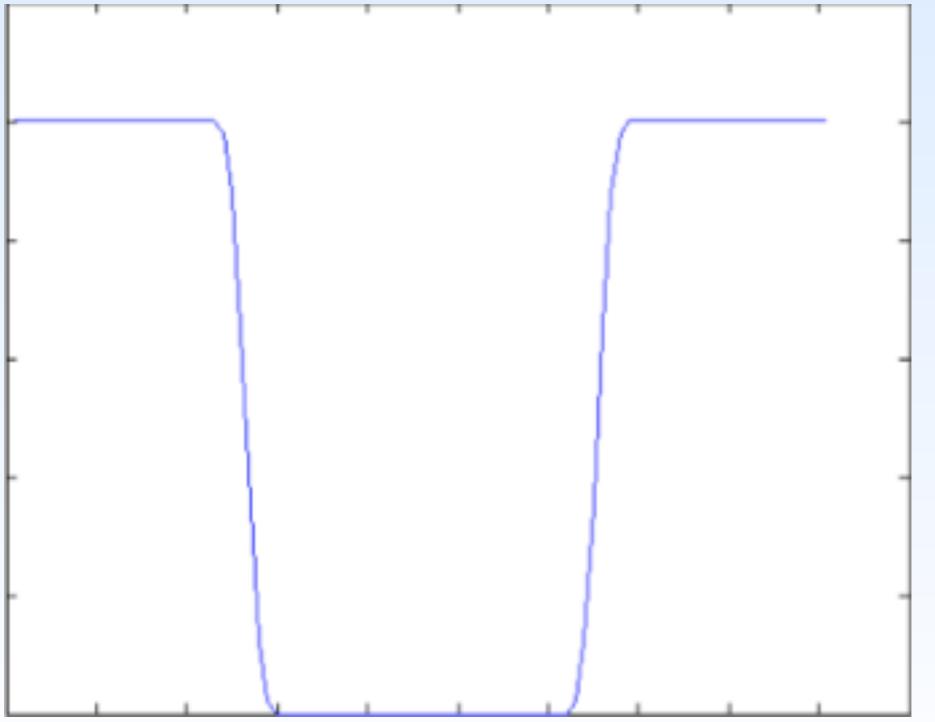

$$\frac{\partial^2 I(x,y)}{\partial x^2} = \nabla^2 I(x, y) = \frac{\partial^2 I}{\partial x^2} + \frac{\partial^2 I}{\partial y^2}$$

# Example images derivatives

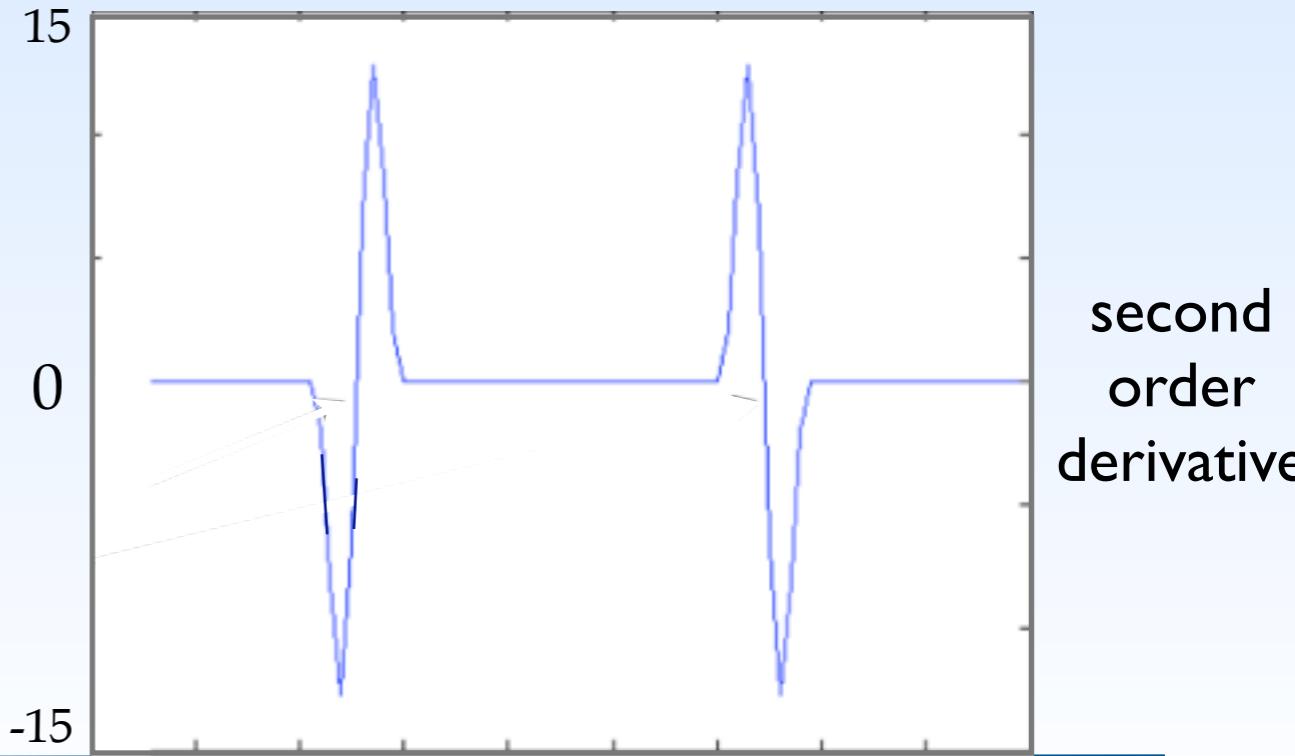

Original  
image

Smoothed  
with  
Gaussian

first  
order  
derivative

second  
order  
derivative

# Second order derivative filters

---

$$\nabla^2 I(x, y) = \frac{\partial^2 I}{\partial x^2} + \frac{\partial^2 I}{\partial y^2}$$

Second order derivative or Laplacian:

$$\frac{\partial^2 I(x_0)}{\partial x^2} = I(x_0 + 2\Delta x) - 2I(x_0 + \Delta x) + I(x_0)$$

can be implemented as simple linear filter:

$$H = \begin{bmatrix} 0 & 1 & 0 \\ 1 & -4 & 1 \\ 0 & 1 & 0 \end{bmatrix} \quad \nabla^2 I = H * I \Rightarrow \\ H \cdot [I(x_0 + 2\Delta x) \ I(x_0 + \Delta x) \ I(x_0)]^T$$

or by separately in x and y direction:

$$H_{xx} = H_{yy}^T = [1 \ -2 \ 1] \quad \nabla^2 I = H_{xx} * I + H_{yy}^T * I$$

# Edge detection

---

To compute image edges we need:

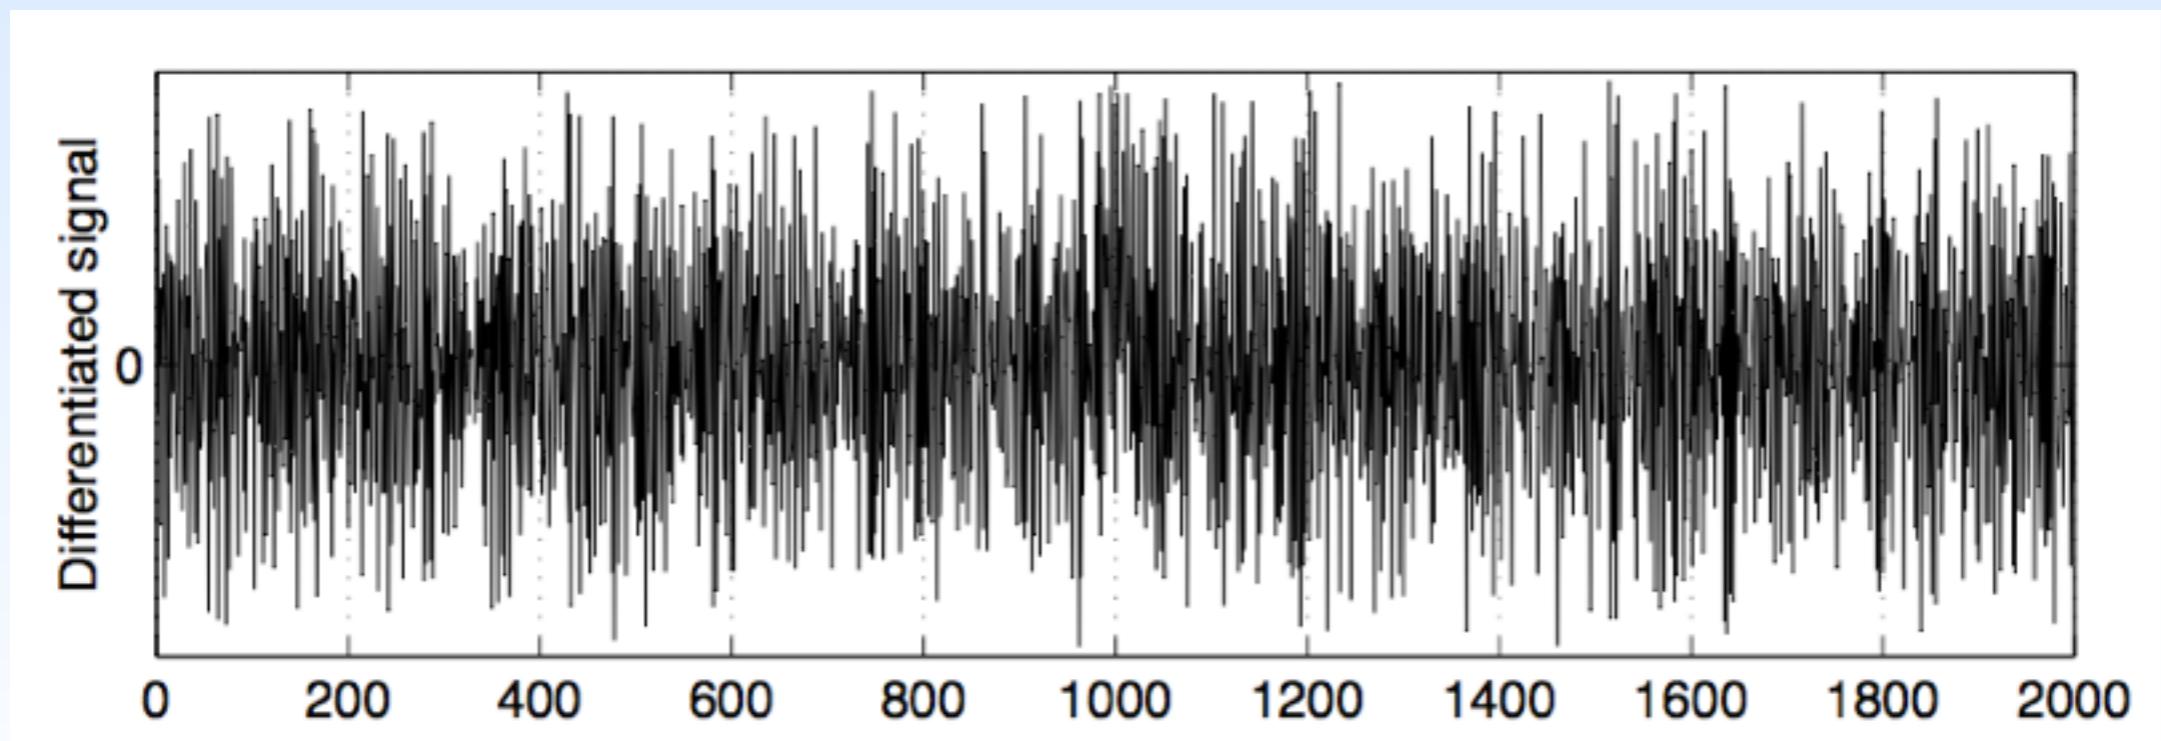

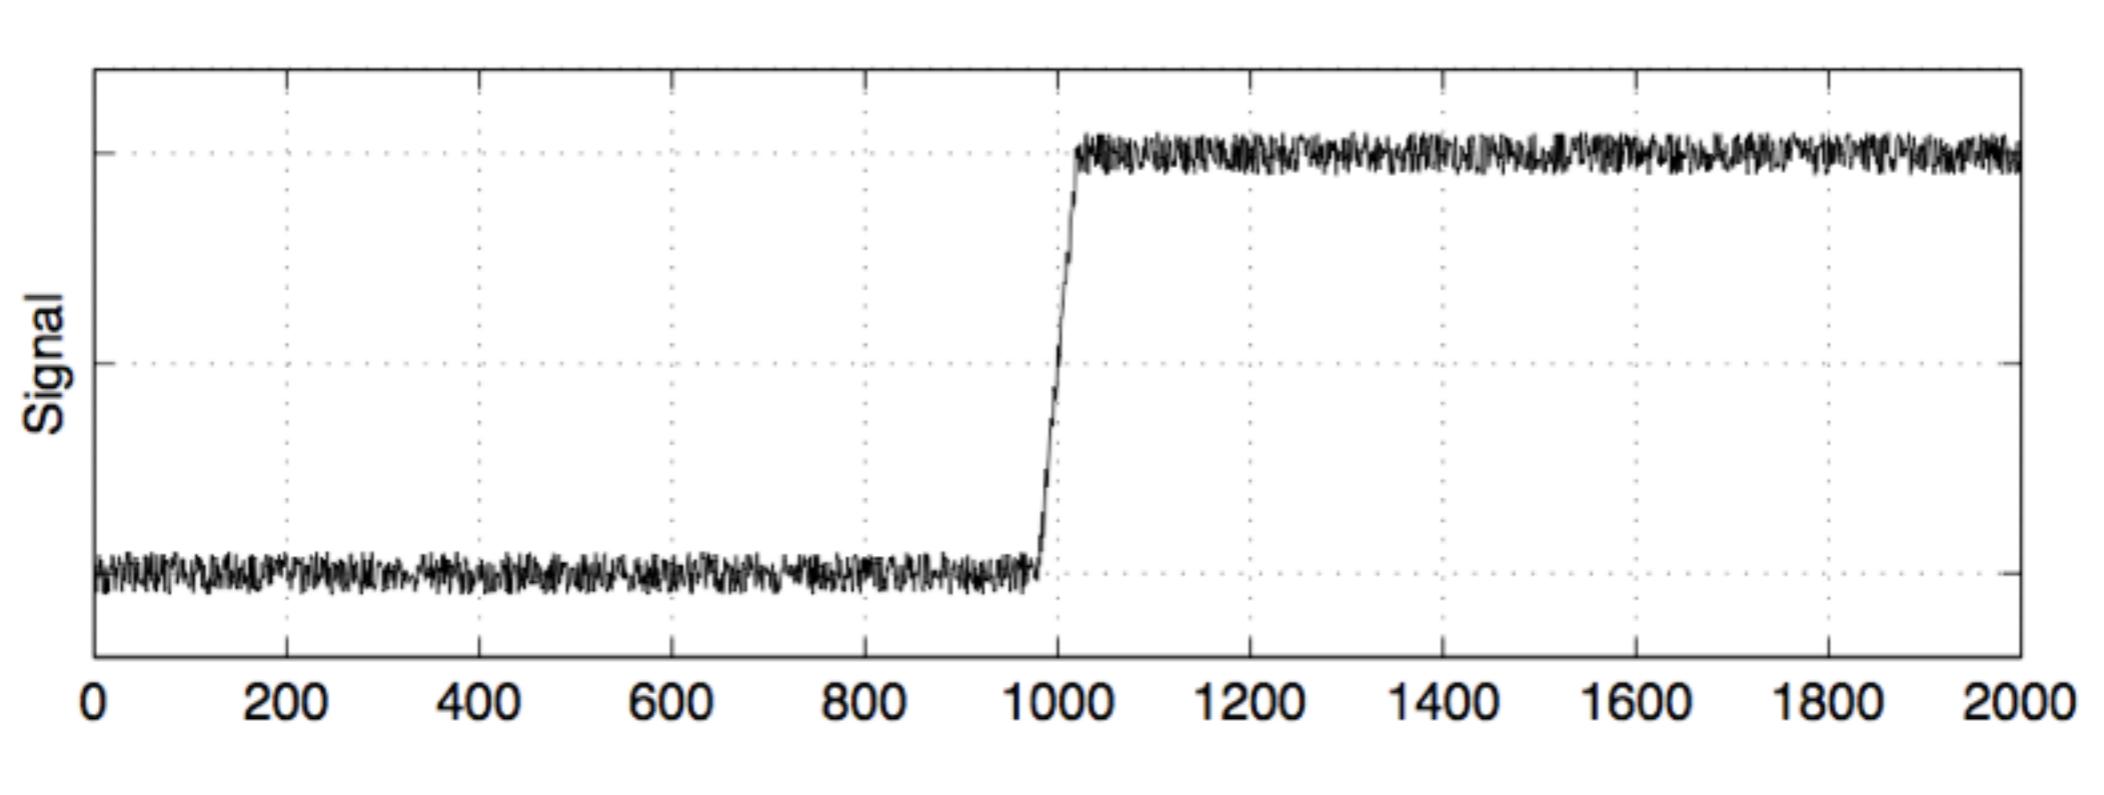

Image smoothing

Image derivatives

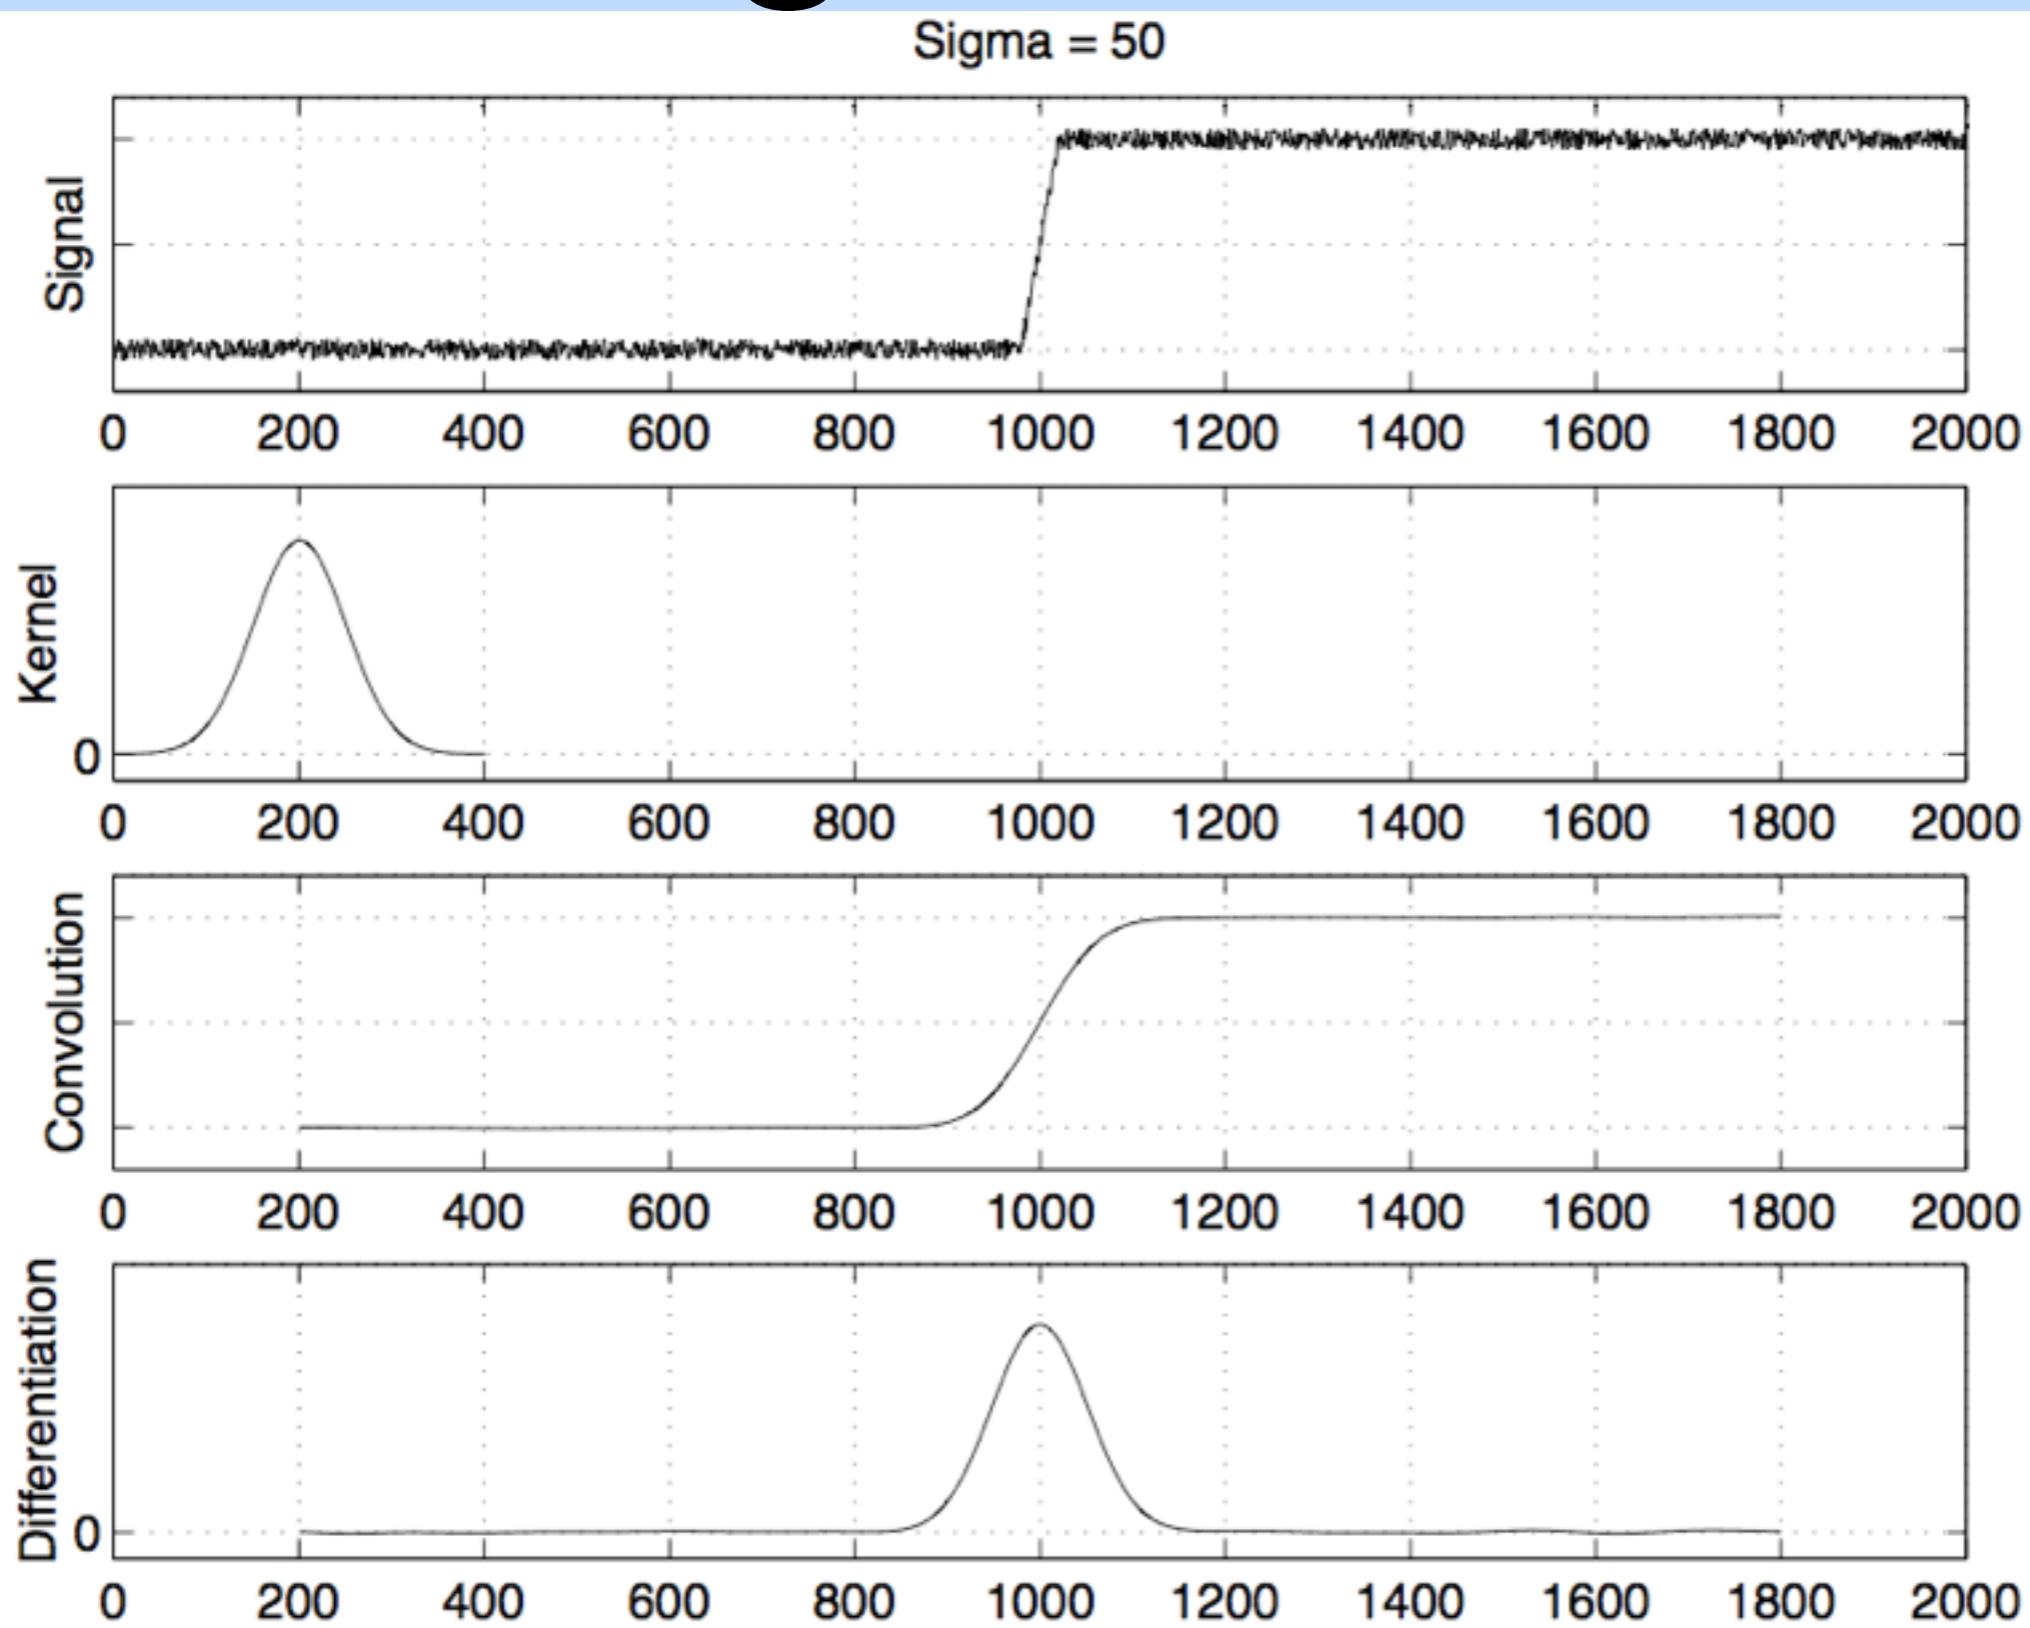

Non-maximal suppression

Thresholding

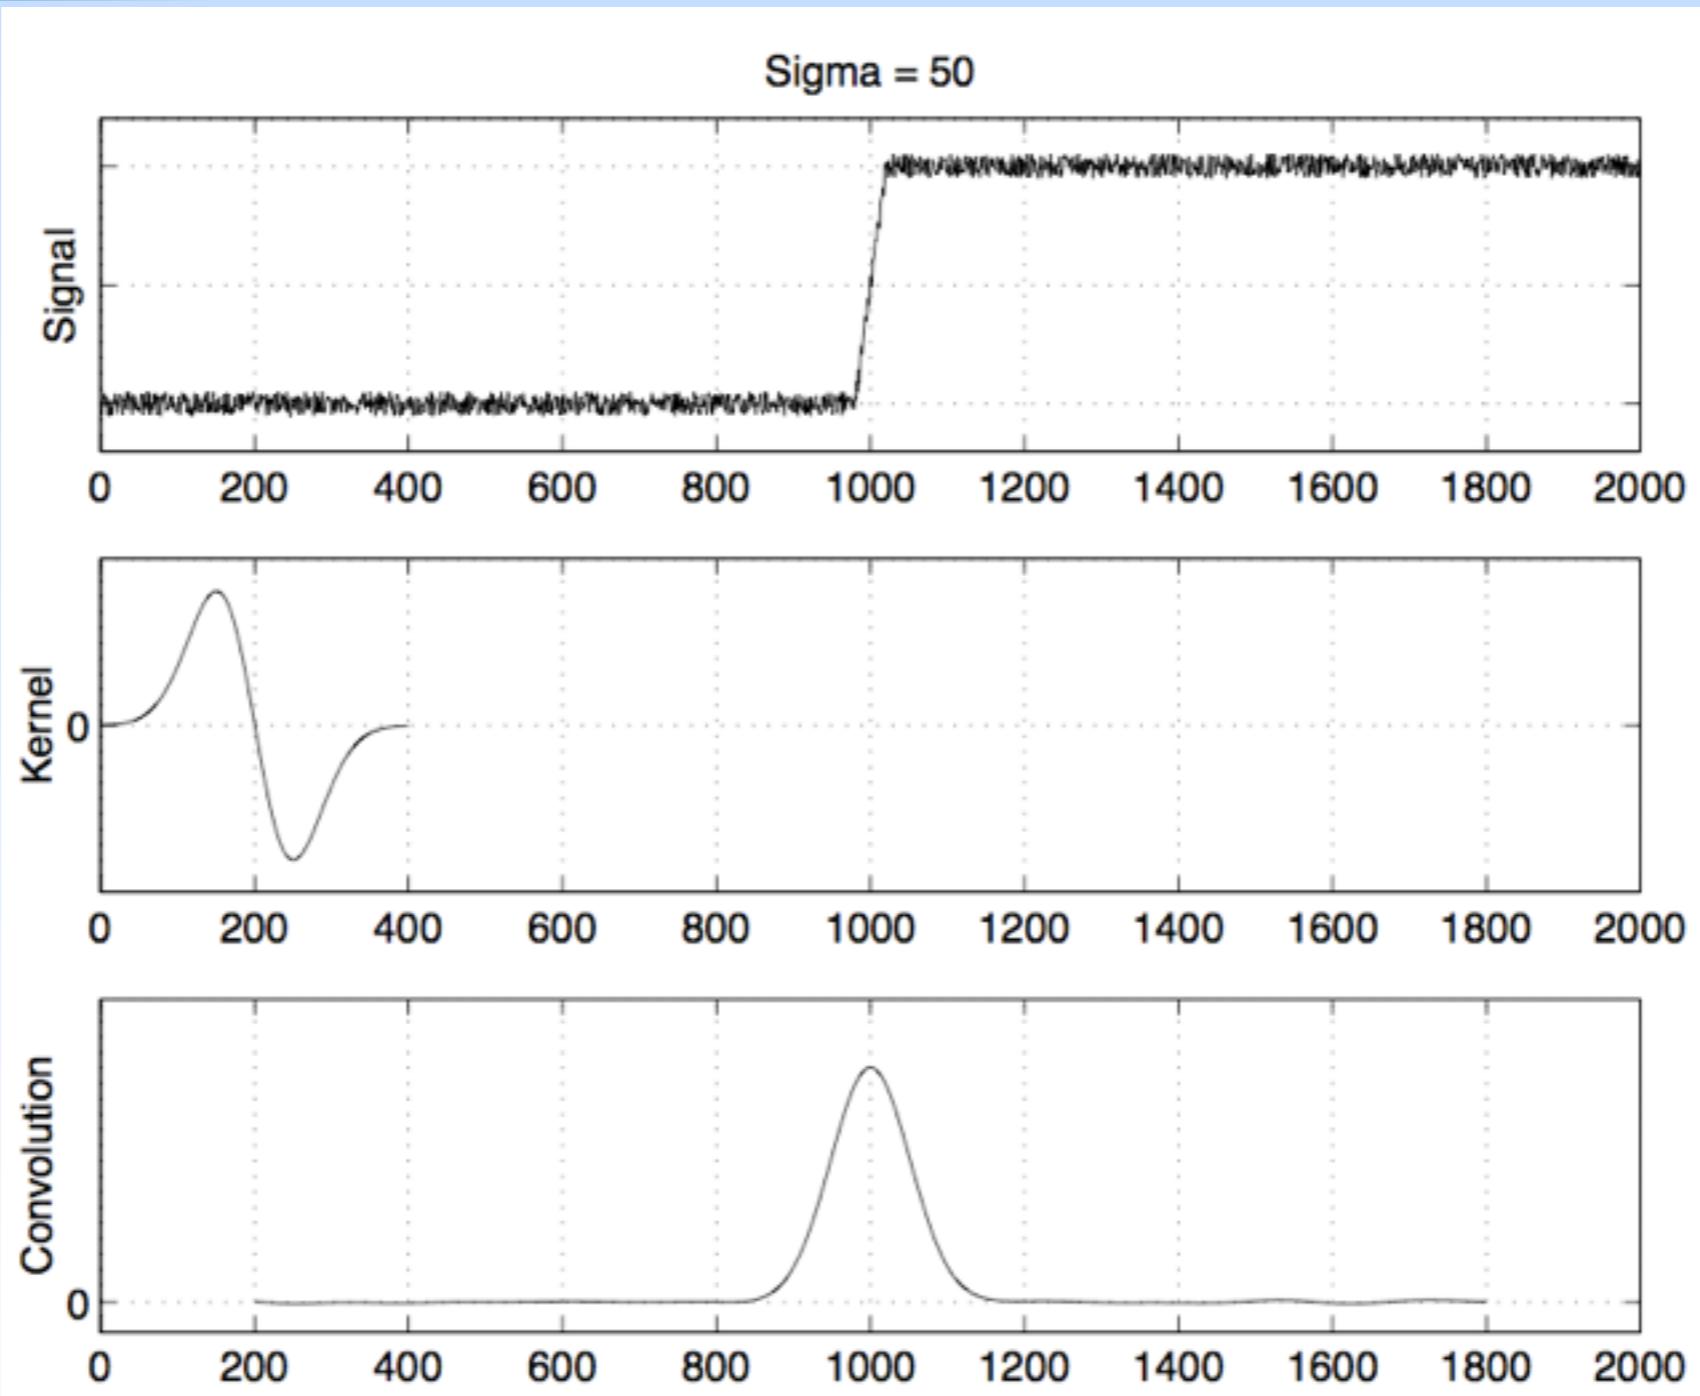

# ID edge detection

# 1D edge detection

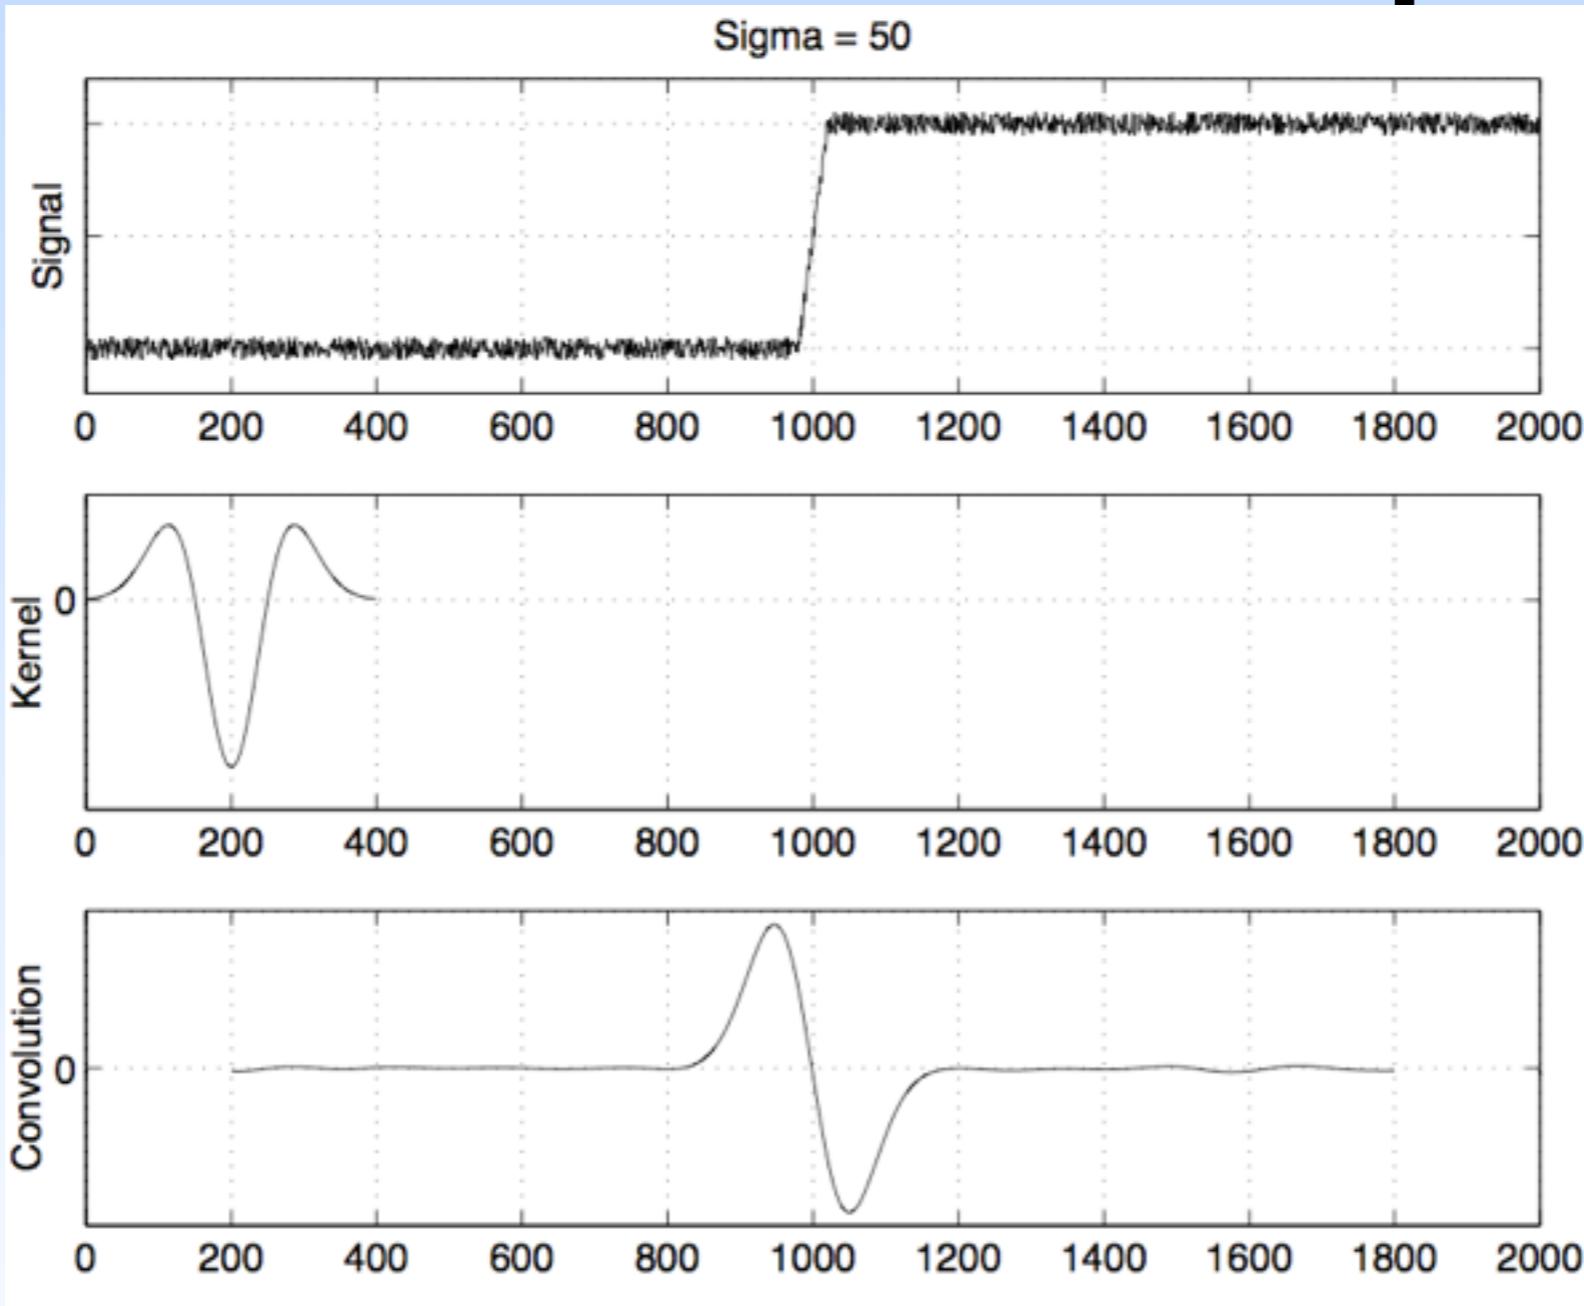

# Convolving with the first order derivative of Gaussian

Smoothing removes noise and amplifies signal at the edge discontinuities.

# Zero crossings and convolution with Laplacian

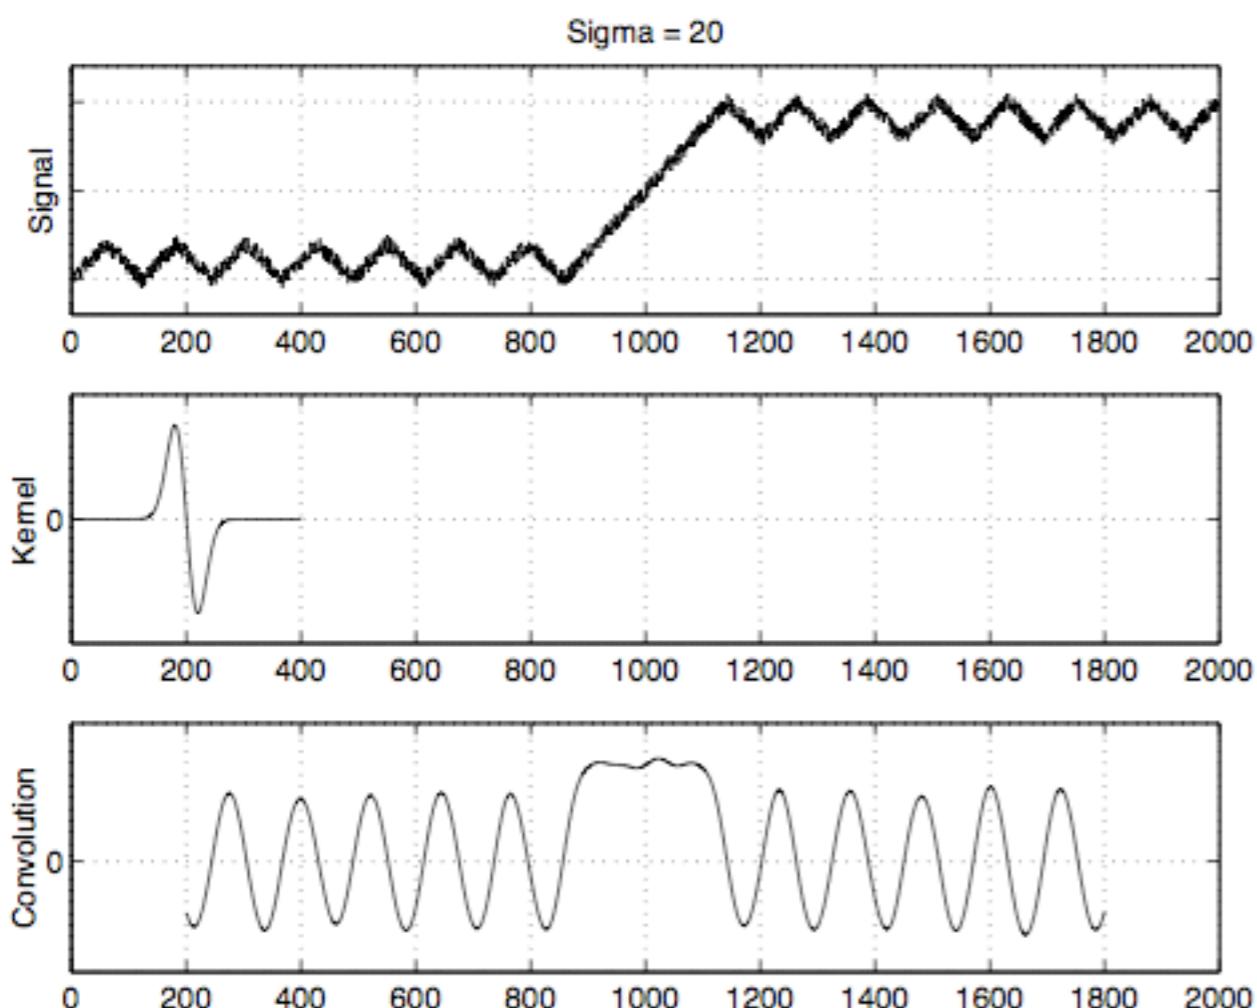

Looking at minima or maxima of first order image derivatives is the same as looking for zero-crossings of second order image derivatives.

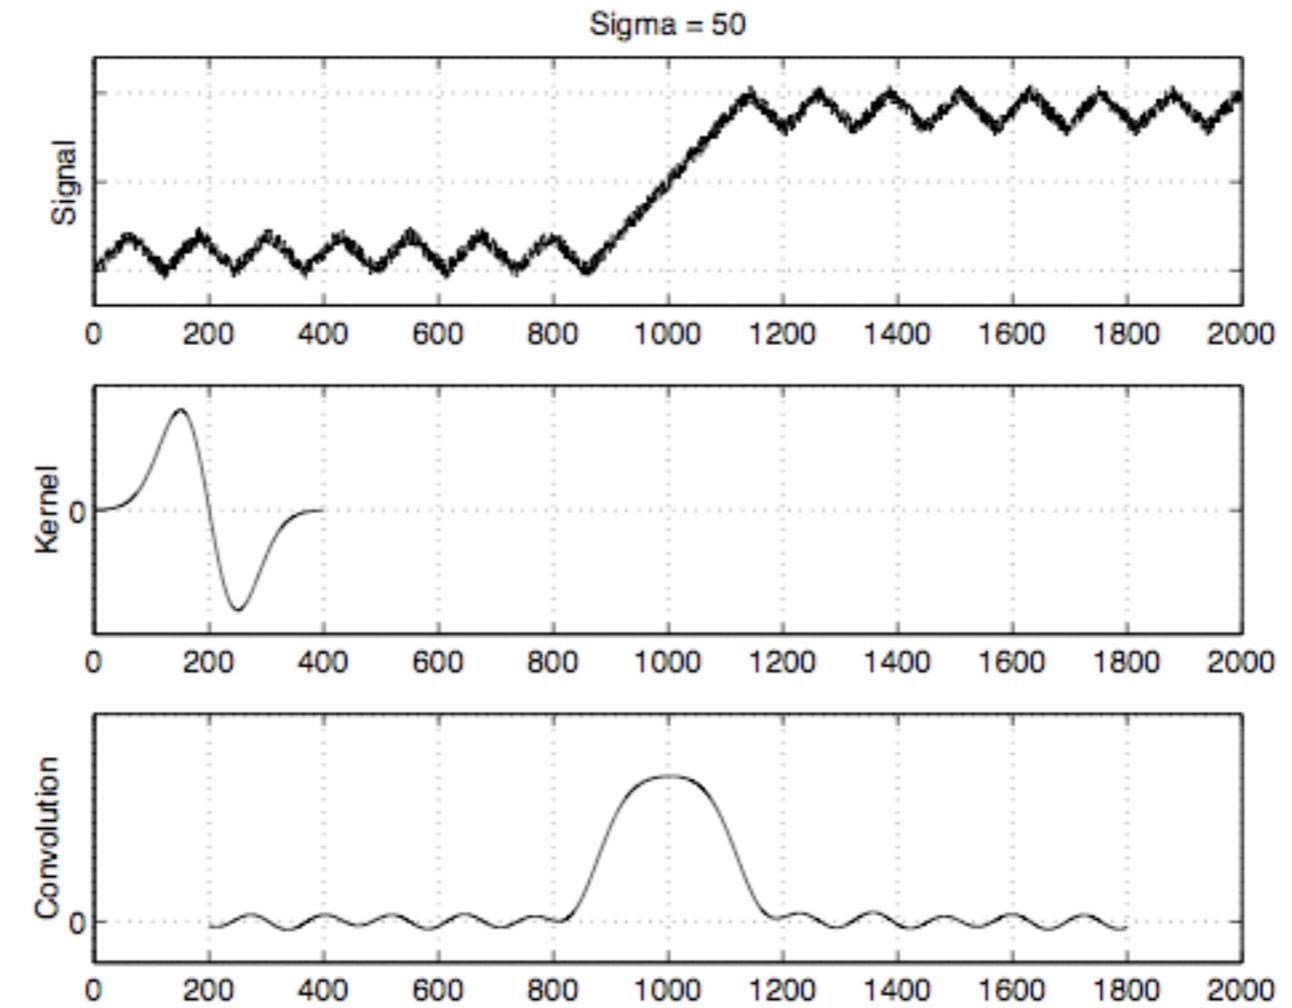

# Multi-scale edge detection

The amount of smoothing controls the scale at which we analyze the image.

Small smoothing brings edges at a fine scale

Signal noise is not suppressed

Increased smoothing suppresses noise

# Non-maximal suppression

original

quantization of  
gradient orientations

gradient  
magnitude

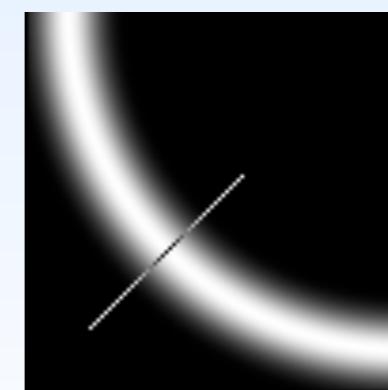

gradients after  
non-maximum suppression

Non-maxima suppression does thinning of the edges.

The gradient orientations are quantized into four bins

Pick neighboring pixels of the edge pixel in the direction of the gradient and take the one with the maximum gradient magnitude, while the others are set to zero.

# Canny edge detection

---

Canny edge detection composes of all already mentioned steps which are:

- Image smoothing
- Image derivatives
- Non-maximal suppression
- Hysteresis thresholding

# Hysteresis thresholding

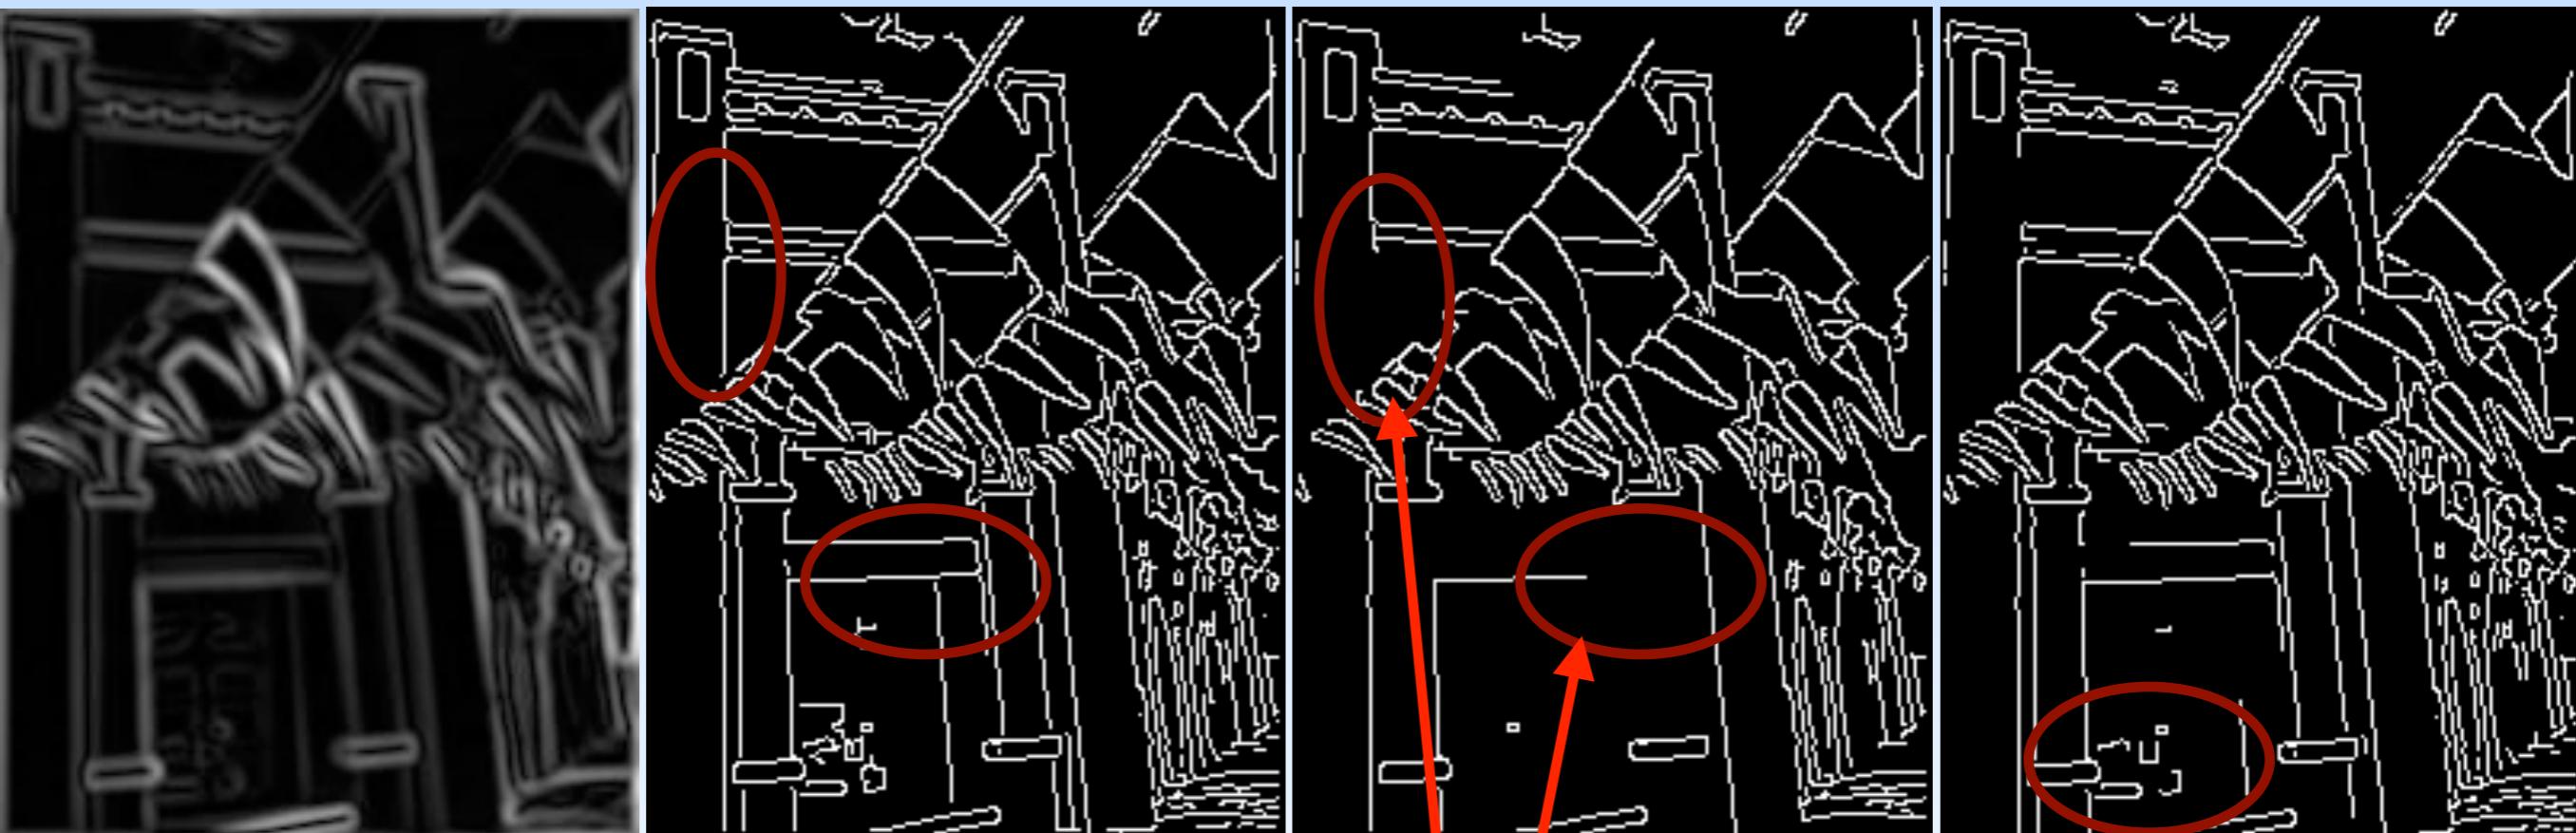

---

Apply two thresholds  $T_{high}$  and  $T_{low}$  to follow edges

Algorithm:

- Search for the pixel with the gradient magnitude value in the non-maximum suppressed image is higher then  $T_{high}$
- Recursively search its neighbors and assign them to the edge if their gradient magnitude value in the non-maximum suppressed image is higher then the  $T_{low}$ .
- otherwise, stop if the gradient magnitude is bellow  $T_{low}$  or the pixel is already visited and assigned to be on an edge and go to 1.

$\text{Th}=50, \text{TI}=40$

Some medium  
strong edges  
disappear

# Non-linear filtering

---

Linear filters combine input pixels in a way that depends on where a pixel is in the image and not on its value

Non-linear filters take into account input pixel values before deciding how to use them in the output.

# Linear vs. non liner filters

filter

median  
filter

# Median Filtering

---

## Example

Original signal:

100 100 100 100 10 10 10 10 10

Noisy signal:

100 103 100 100 10 9 10 11 10

Filter by [ 1 1 1]/3:

101 101 70 40 10 10 10

Filter by 1x3 median filter:

100 100 100 10 10 10 10

# Median Filter

---

- Median filters are nonlinear
- Median filtering reduces noise without blurring edges and other sharp details
- Median filtering is particularly effective when the noise pattern consists of strong, spike-like components. (Salt-and-pepper noise.)

# Bilateral filter

---

It is nonlinear filtering technique based on:

**Domain(smoothing) filter** - It is based on *closeness* function which accounts for spacial distance between the central pixel  $\mathbf{x}$  and its neighbors  $\xi$

$$c(\xi, \mathbf{x}) = e^{-\frac{1}{2} \left( \frac{d(\xi, \mathbf{x})}{\sigma_d} \right)^2}, \quad d(\xi, \mathbf{x}) = \|\xi - \mathbf{x}\|$$

**Range filter** - It is based on the *similarity* function between image intensities between the central pixel  $I(\mathbf{x})$  and its neighbors  $I(\xi)$

$$s(\xi, \mathbf{x}) = e^{-\frac{1}{2} \left( \frac{\delta(I(\xi), I(\mathbf{x}))}{\sigma_r} \right)^2}, \quad \delta(I(\xi), I(\mathbf{x})) = \|I(\xi) - I(\mathbf{x})\|$$

$\sigma_d$  - desired amount of spacial smoothing    $\sigma_r$  - desired amount of combining of pixel values

# Bilateral filter

---

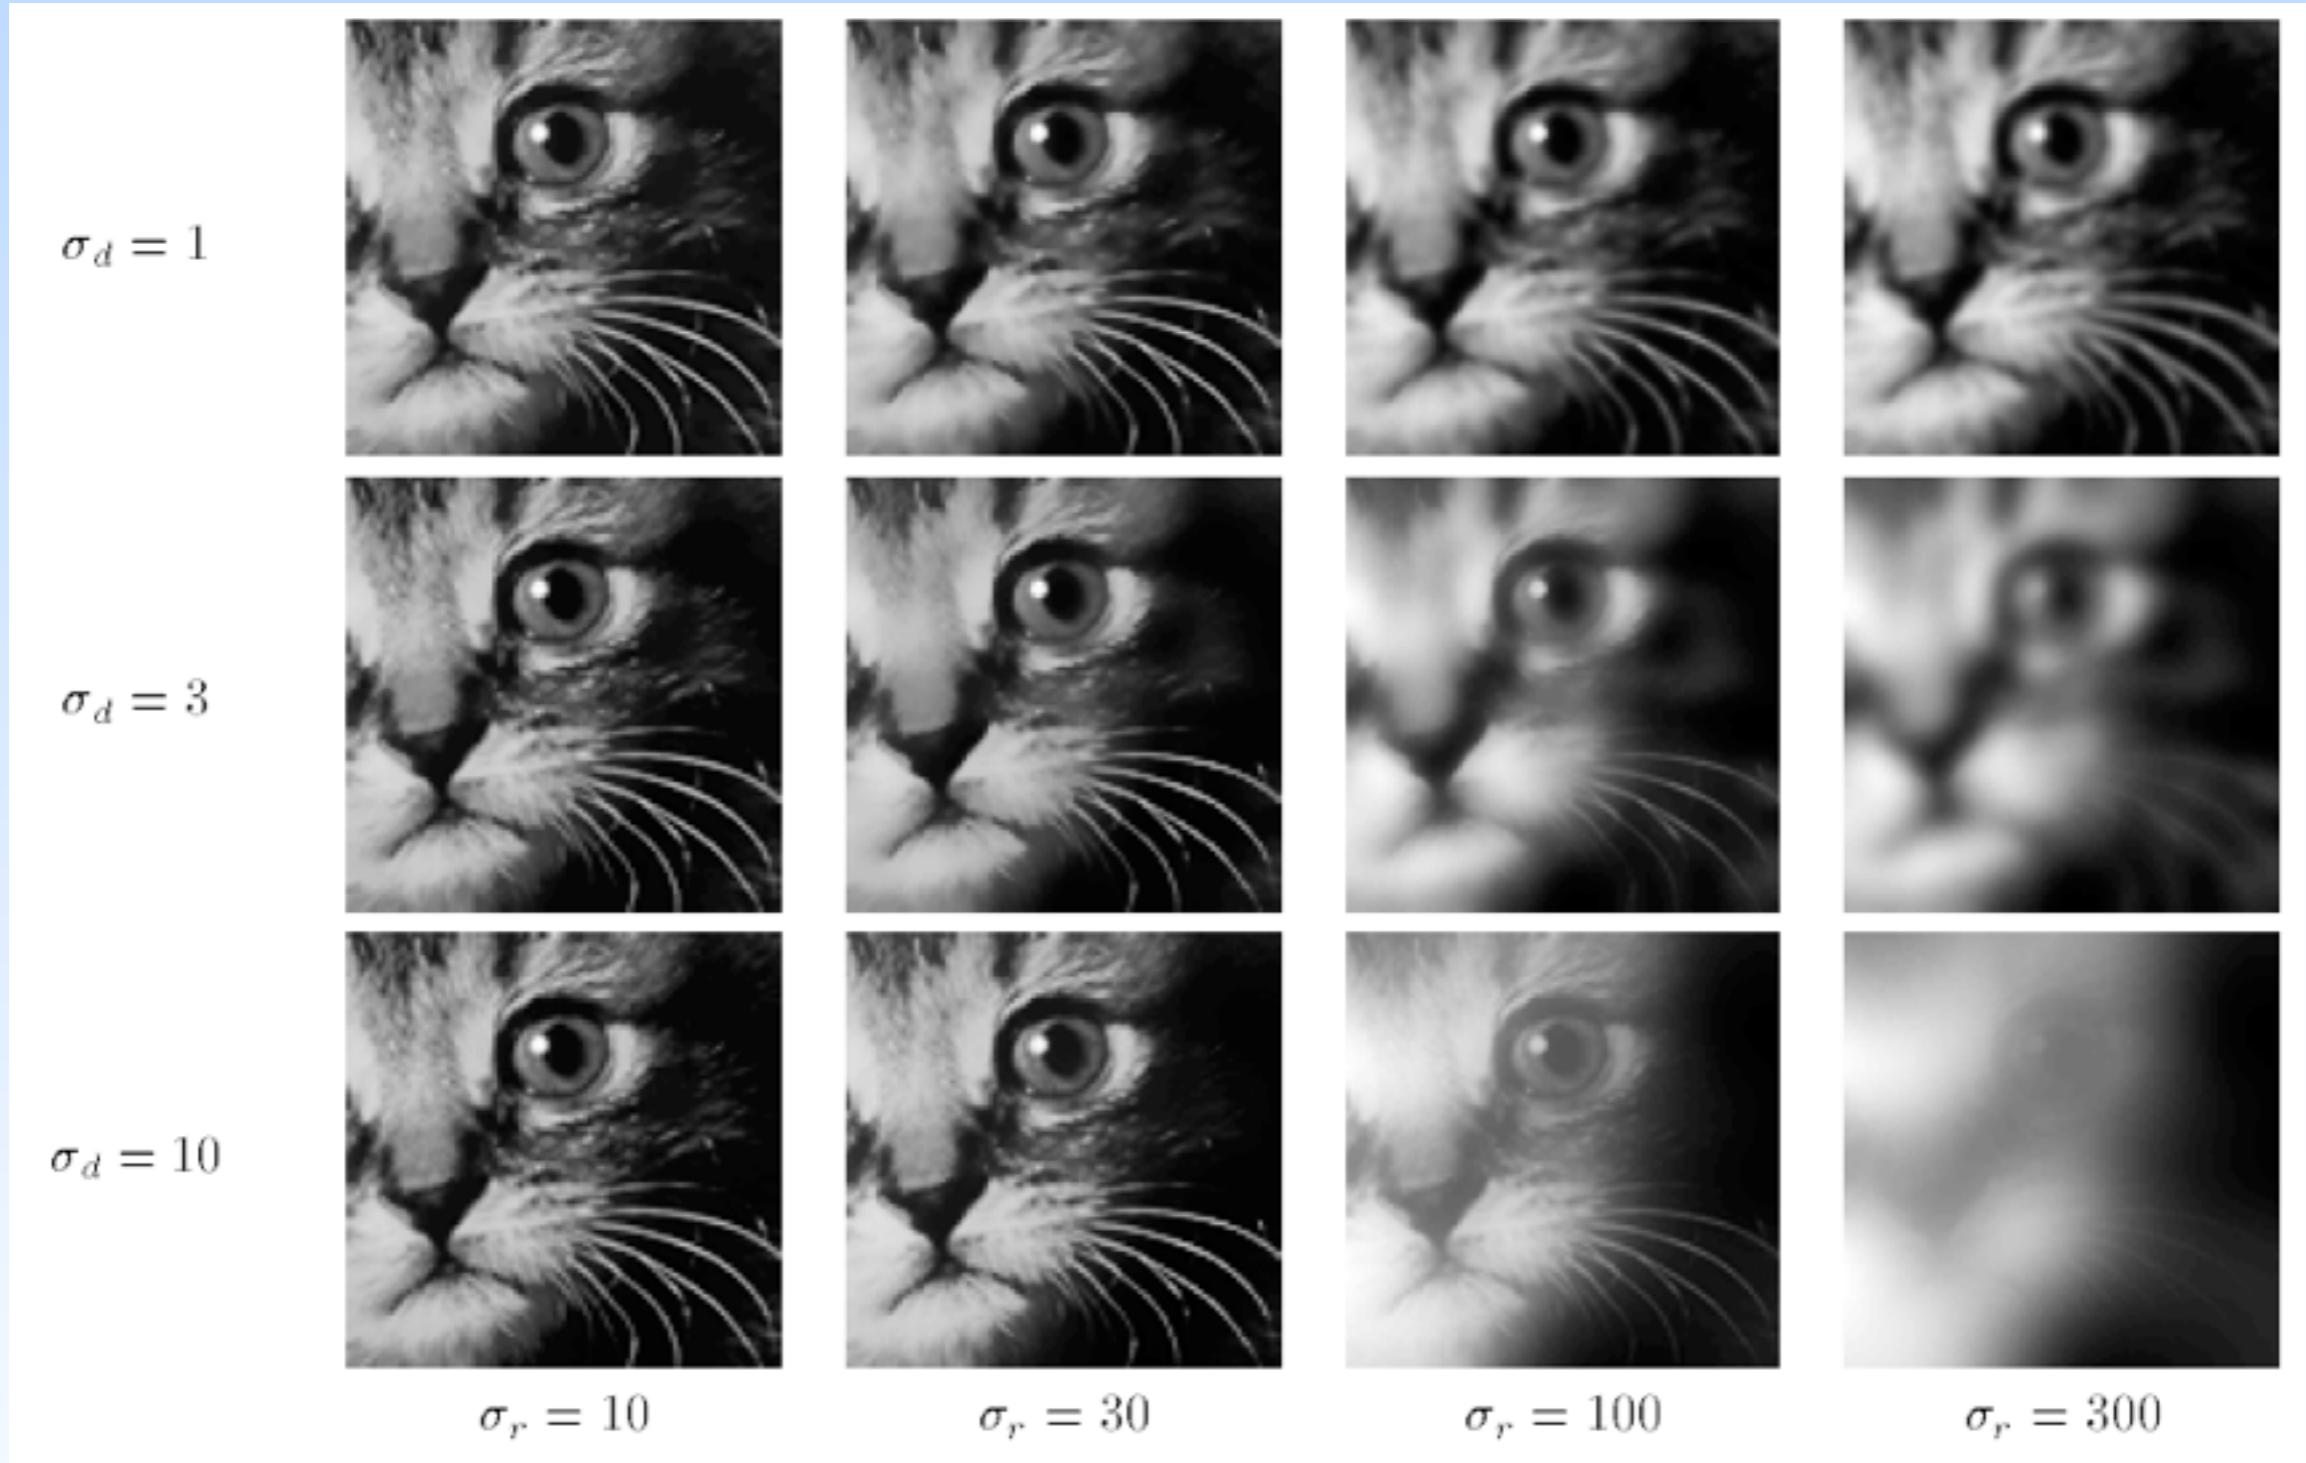

Combining similarity and closeness functions we obtain:

$$h(\mathbf{x}) = \frac{1}{c} \sum_{\xi \in \Omega} I(\xi) c(\xi, \mathbf{x}) s((I(\xi), I(\mathbf{x})))$$

$$c = \sum_{\xi \in \Omega} c(\xi, \mathbf{x}) s((I(\xi), I(\mathbf{x})))$$

This filter is known to reduce

- noise and
- to preserve edges
